**Description**

Implementation of Trellis Graphics in R

**Details**

Trellis Graphics is a framework for data visualization developed at the Bell Labs by Rick Becker, Bill Cleveland et al, extending ideas presented in Bill Cleveland’s 1993 book *Visualizing Data*. Lattice is best thought of as an implementation of Trellis Graphics for R. Its interface is based on the implementation in S-PLUS, but there are several differences. To the extent possible, care has been taken to ensure that existing Trellis code written for S-PLUS works unchanged (or with minimal change) in Lattice. If you are having problems porting S-PLUS code, read the entry for `panel` in the documentation for `xyplot`. Most high level Trellis functions in S-PLUS are implemented, with the exception of `piechart`.

Lattice is built upon the Grid Graphics engine for R being developed by Paul Murrell and requires the `grid` add-on package.

Type `help(package = lattice)` to see a list of (public) Lattice graphics functions for which further documentation is available. The ‘See Also’ section below has list of specific areas of possible interest and pointers to the help pages with respective details. Apart from the documentation accompanying this package, several documents outlining the use of Trellis graphics is available from Bell Lab’s website that might provide a holistic introduction to the Trellis paradigm. The example section shows how to bring up a brief history of changes to the lattice package, which provides a summary of new features.

**Note**

High level Lattice functions (like `xyplot`) are different from conventional R graphics functions because they don’t actually draw anything. Instead, they return an object of class "trellis" which has to be then printed or plotted to create the actual plot. This is normally done automatically, but not when the high level functions are called inside another function (most often `source`) or other contexts where automatic printing is suppressed (e.g. `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

Lattice plots are highly customizable via user-modifiable settings. However, these are completely unrelated to base graphics settings; in particular, changing `par()` settings usually have no effect on lattice plots.

See Also

The Lattice user interface primarily consists of several ‘high level’ generic functions (listed below), each designed to create a particular type of statistical display by default. While each function does different things, they share several common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`. This includes a discussion of conditioning and control of the Trellis layout.

Lattice employs an extensive system of user-controllable parameters to determine the look and feel of the displays it produces. To learn how to use and customise the Graphical parameters used by the Lattice functions, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are different for different graphical devices. To learn how to initialise new devices with the desired settings or change the settings of the current device, see `trellis.device`.

To learn about sophisticated (non-default) printing capabilities, see `print.trellis`. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including locator-like functionality) is described in the `interaction` help page.

The following is a list of ‘high level’ functions in the Lattice package with a brief description of what they do. In all cases, the actual display is produced by the so-called panel function, which has a suitable default, but can be substituted by an user defined function to create custom displays. The user will most often be interested in the default panel functions, which have a separate help page, linked to from the help pages of the corresponding high level function. Although documented separately, arguments to these panel functions can be supplied directly to the high level functions, which will forward the arguments as appropriate.

Univariate:
- `barchart` bar plots
- `bwplot` box and whisker plots
- `densityplot` kernel density plots
- `dotplot` dot plots
- `histogram` histograms
- `qqmath` quantile plots against mathematical distributions
- `stripplot` 1-dimensional scatterplot

Bivariate:
- `qq` q-q plot for comparing two distributions
- `xyplot` scatter plot (and possibly a lot more)

Trivariate:
levelplot level plots (similar to image plots in R)
contourplot contour plots
cloud 3-D scatter plots
wireframe 3-D surfaces (similar to persp plots in R)

Hypervariate:
splom scatterplot matrix
parallel parallel coordinate plots

Miscellaneous:
rfs residual and fitted value plot (also see oneway)
tmd Tukey Mean-Difference plot

Additionally, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in panel.functions. Lattice also has a collection of convenience functions that correspond to the base graphics primitives lines, points, etc. They are implemented using Grid graphics, but try to be as close to the base versions as possible in terms of their argument list. These functions have imaginative names like llines or panel.lines and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Examples

```r
## Not run:
## brief history of changes
file.show(system.file("Changes", package = "lattice"))
## End(Not run)
```

---

**Rows**

*Extract rows from a list*

---

**Description**

Convenience function to extract subset of a list. Usually used in creating keys.

**Usage**

```r
Rows(x, which)
```

**Arguments**

- `x`: list with each member a vector of the same length
- `which`: index for members of `x`

**Value**

A list similar to `x`, with each `x[[i]]` replaced by `x[[i]][which]`

axis.default Default axis annotation utilities

Description
Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The xscale.components and yscale.components arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the axis argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

Usage

```r
xscale.components.default(lim, 
    packet.number = 0, 
    packet.list = NULL, 
    top = TRUE, 
    ...
)
yscale.components.default(lim, 
    packet.number = 0, 
    packet.list = NULL, 
    right = TRUE, 
    ...
)
axis.default(side = c("top", "bottom", "left", "right"), 
    scales, components, as.table, 
    labels = c("default", "yes", "no"), 
    ticks = c("default", "yes", "no"), 
    ...
)
```

Arguments

- **lim**
  the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.
**packet.number**

which packet (counted according to the packet order, described in **print.trellis**) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.

**packet.list**

list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)

**top, right**

the value of the top and right components of the result, as appropriate. See below for interpretation.

**side**

on which side the axis is to be drawn. The usual partial matching rules apply.

**scales**

the appropriate component of the scales argument supplied to the high level function, suitably standardized.

**components**

list, similar to those produced by xscale.components.default and yscale.components.default.

**as.table**

the as.table argument in the high level function.

**labels**

whether labels are to be drawn. By default, the rules determined by scales are used.

**ticks**

whether labels are to be drawn. By default, the rules determined by scales are used.

... many other arguments may be supplied, and are passed on to other internal functions.

**Details**

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

**Value**

xscale.components.default and yscale.components.default return lists in a specific format expected by axis.default. The exact form will be documented later.

### Banking

#### Description
Calculates banking slope

#### Usage
```
banking(dx, dy)
```

#### Arguments
- `dx`, `dy` vector of consecutive x, y differences.

#### Details
`banking` is the banking function used when `aspect = "xy"` in high level Trellis functions. It is usually not very meaningful except with `xyplot`. It considers the absolute slopes (based on `dx` and `dy`) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.
This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs’ website (see Lattice), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying lattice.options("banking").

Lattice, xyplot

Examples

```r
xyplot(sunspot.year ~ time(sunspot.year) | equal.count(time(sunspot.year)),
  xlab = "", type = "l", aspect = "xy", strip = FALSE,
  scales = list(x = list(alternating = 2, relation = "sliced")),
  as.table = TRUE, main = "Yearly Sunspots")
```

Description

Contingency tables are often displayed using barcharts and dotplots. These methods are provided for convenience and operate directly on tables. Arrays and matrices are simply coerced to be a table.

Usage

```r
## S3 method for class 'table':
barchart(x, data, groups = TRUE,
  origin = 0, stack = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array':
barchart(x, data, ...)

## S3 method for class 'matrix':
barchart(x, data, ...)
```
## S3 method for class 'table':
dotplot(x, data, groups = TRUE, ...)

## S3 method for class 'array':
dotplot(x, data, ...)

## S3 method for class 'matrix':
dotplot(x, data, ...)

### Arguments

- **x**  
a table, array or matrix object.
- **data**  
should not be specified. If specified, will be ignored with a warning.
- **groups**  
logical, whether to use the last dimension as the grouping variable in the display.
- **origin, stack**  
arguments to panel.barchart controlling the display. The defaults for the table method are different.
- **horizontal**  
logical, indicating whether the bars should be horizontal or vertical
- **...**  
other arguments, passed to the underlying formula method.

### Details

The first dimension is used as the variable on the vertical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument using \texttt{t} or \texttt{aperm}). For more flexibility, use the formula method after converting the table to a data frame using the relevant \texttt{as.data.frame} method.

### Value

An object of class "trellis". The \texttt{update} method can be used to update components of the object and the \texttt{print} method (usually called by default) will plot it on an appropriate plotting device.

\texttt{ auto.key = list(title = "Survived"))}
barley

*Yield data from a Minnesota barley trial*

---

**Description**

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

**Usage**

barley

**Format**

A data frame with 120 observations on the following 4 variables.

- **yield**  Yield (averaged across three blocks) in bushels/acre.
- **variety**  Factor with levels "Svensota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Trebi".
- **year**  Factor with levels 1932, 1931
- **site**  Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

**Details**

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year*Site*Variety*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

`immer` in the MASS package for data from the same experiment (expressed as total yield for 3 blocks) for a subset of varieties.

Examples

```r
# Graphic suggesting the Morris data switched the years 1931 and 1932
# Figure 1.1 from Cleveland
dotplot(variety ~ yield | site, data = barley, groups = year,
       key = simpleKey(levels(barley$year), space = "right"),
       xlab = "Barley Yield (bushels/acre) ",
       aspect=0.5, layout = c(1,6), ylab=NULL)
```

cloud 3d Scatter Plot and Wireframe Surface Plot

Description

Generic functions to draw 3d scatter plots and surfaces. The "formula" methods do most of the actual work.

Usage

```r
cloud(x, data, ...)
wireframe(x, data, ...)
```

```r
## S3 method for class 'formula':
cloud(x, data,
     allow.multiple = is.null(groups) || outer,
     outer = FALSE,
     auto.key = FALSE,
     aspect = c(1,1),
     panel.aspect = 1,
     panel = lattice.getOption("panel.cloud"),
     prepanel = NULL,
     scales = list(),
     strip = TRUE,
     groups = NULL,
     xlab, ylab, zlab,
     
```
cloud

xlim = if (is.factor(x)) levels(x) else range(x, finite = TRUE),
ylim = if (is.factor(y)) levels(y) else range(y, finite = TRUE),
zlim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
at,
drape = FALSE,
pretty = FALSE,
drop.unused.levels,
...

## S3 method for class 'formula':
wireframe(x,
data,
panel = lattice.getOption("panel.wireframe"),
...)

## S3 method for class 'matrix':
cloud(x, data = NULL, type = "h",
zlab = deparse(substitute(x)), aspect, ...
row.values, column.values)

## S3 method for class 'table':
cloud(x, data = NULL, groups = FALSE,
zlab = deparse(substitute(x)),
type = "h", ...)

## S3 method for class 'matrix':
wireframe(x, data = NULL,
zlab = deparse(substitute(x)), aspect, ...
row.values, column.values)

Arguments

x

The object on which method dispatch is carried out.

For the "formula" methods, a formula of the form z ~ x * y | g1 * g2 * ...; where z is a numeric response, and x, y are numeric values. g1, g2, ... if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of wireframe, calculations are based on the assumption that the x and y values are evaluated on a rectangular grid.
defined by their unique values. The grid points need not be equally spaced.

For wireframe, x, y and z may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.

Missing values are allowed, either as NA values in the z vector, or missing rows in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in z are.

Both wireframe and cloud have methods for matrix objects, in which case x provides the z vector described above, while its rows and columns are interpreted as the x and y vectors respectively. This is similar to the form used in persp.

data

for the "formula" methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. data should not be specified except when using the "formula" method.

row.values, column.values

Optional vectors of values that define the grid when x is a matrix. row.values and column.values must have the same lengths as nrow(x) and ncol(x) respectively. By default, row and column numbers.

allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset

These arguments are documented in the help page for xyplot. For the cloud.table method, groups must be a logical indicating whether the last dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.

type
type of display in cloud (see panel.3dscatter for details). Defaults to "h" for the matrix method.

aspect, panel.aspect

Unlike other high level functions, aspect is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the aspect argument in determining the aspect ratio of the panel (see xyplot for details) is played by panel.aspect, except that it can only be a numeric value.

For the matrix methods, the default y/x aspect is ncol(x) / nrow(x) and the z/x aspect is the smaller of the y/x aspect and 1.

panel

panel function used to create the display. See panel.cloud for (non-trivial) details.

tscales

a list describing the scales. As with other high level functions (see xyplot for details), this list can contain parameters in name=value form. It can also contain components with the special names x, y and z, which can be similar lists with axis-specific values overriding the ones specified in scales.

The most common use for this argument is to set arrows=FALSE, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by draw=FALSE. Another special component is distance, which specifies the relative distance of the axis label from the bounding box. If specified as a component of scales (as opposed to one of
scales$z etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the x, y and z labels respectively.

Other components that work in the scales argument of xyplot etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)

Note, however, that for these functions scales cannot contain information that is specific to particular panels. If you really need that, consider using the scales.3d argument of panel.cloud.

axs.default Unlike 2-D display functions, cloud does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in wireframe, which uses the same code. axs.default is intended to provide a different default for cloud. However, this feature has not yet been implemented.

zlab Specifies a label describing the z variable in ways similar to xlab and ylab (i.e. “grob”, character string, expression or list) in other high level functions. Additionally, if zlab (and xlab and ylab) is a list, it can contain a component called rot, controlling the rotation for the label.

zlim limits for the z-axis. Similar to xlim and ylim in other high level functions.

drape logical, whether the wireframe is to be draped in color. If TRUE, the height of a facet is used to determine its color in a manner similar to the coloring scheme used in levelplot. Otherwise, the background color is used to color the facets. This argument is ignored if shade = TRUE (see panel.3dwire).

at, col.regions, alpha.regions these arguments are analogous to those in levelplot. if drape=TRUE, at gives the vector of cutpoints where the colors change, and col.regions the vector of colors to be used in that case. alpha.regions determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for col.regions and alpha.regions is derived from the Trellis setting "regions".

cuts if at is unspecified, the approximate number of cutpoints if drape=TRUE

pretty whether automatic choice of cutpoints should be prettfied

colorkey logical indicating whether a color key should be drawn alongside, or a list describing such a key. See levelplot for details.

... Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments distance, perspective, screen and R.mat are very important in determining the 3-D display. The argument shade can be useful for wireframe calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for panel.cloud.

Additionally, an argument called zoom may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default prepanel function.
Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the [-0.5, 0.5] cube (even smaller for non-default values of \(\text{aspect}\)). The viewing direction is given by a sequence of rotations specified by the \text{screen} argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of \(1/\text{distance}\) from the origin. If \text{perspective} = \text{FALSE}, distance is set to 0 (i.e., the viewing point is at an infinite distance).

c cloud draws a 3-D Scatter Plot, while \text{wireframe} draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by \text{wireframe} using the \text{groups} argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying \text{groups} with \text{cloud} results in a \text{panel.superpose}-like effect (via \text{panel.3dscatter}).

\text{wireframe} can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for \text{panel.3dwire}. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to \text{cloud} and \text{wireframe} directly.

For single panel plots, \text{wireframe} can also plot parametrized 3-D surfaces (i.e., functions of the form \(f(u,v) = (x(u,v), y(u,v), z(u,v))\), where values of \((u,v)\) lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling \text{wireframe} with a formula \text{x} of the form \(z \sim x + y\), where \(x\), \(y\) and \(z\) are all matrices of the same dimension, representing the values of \(x(u,v), y(u,v)\) and \(z(u,v)\) evaluated on a discrete rectangular grid (the actual values of \((u,v)\) are irrelevant).

When this feature is used, the heights used to calculate \text{drape} colors or shading colors are no longer the \(z\) values, but the distances of \((x, y, z)\) from the origin.

Note that this feature does not work with \text{groups}, \text{subscripts}, \text{subset}, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, \text{panel.cloud} tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the \text{scpos} argument in \text{panel.cloud}.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for \text{xypplot}, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The \text{update} method can be used to update components of the object and the \text{print} method (usually called by default) will plot it on an appropriate plotting device.

Note

There is a known problem with grouped \text{wireframe} displays when the \((x, y)\) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the \text{groups} argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a
meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

**draw.colorkey**  
*Produce a Colorkey for levelplot*

**Description**

Produces (and possibly draws) a Grid frame grob which is a colorkey that can be placed in other Grid plots. Used in levelplot.

**Usage**

`draw.colorkey(key, draw=FALSE, vp=NULL)`

**Arguments**

- `key`  
  A list determining the key. See documentation for `levelplot`, in particular the section describing the `colorkey` argument, for details.

- `draw`  
  logical, whether the grob is to be drawn.

- `vp`  
  viewport

**Value**

A Grid frame object (that inherits from "grob")

**Author(s)**

Deepayan Sarkar  
(Deepayan.Sarkar@R-project.org)

**See Also**

`xyplot`
draw.key  Produce a Legend or Key

Description

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

Usage

draw.key(key, draw=FALSE, vp=NULL)

Arguments

key  A list determining the key. See documentation for \texttt{xyplot}, in particular the section describing the \texttt{key} argument, for details.
draw  logical, whether the grob is to be drawn.
vp  viewport

Value

A Grid frame object (that inherits from ‘grob’).

environmental  Atmospheric environmental conditions in New York City

Description

Usage

environmental
Format

A data frame with 111 observations on the following 4 variables.

- **ozone**: Average ozone concentration (of hourly measurements) of in parts per billion.
- **radiation**: Solar radiation (from 08:00 to 12:00) in langleys.
- **temperature**: Maximum daily temperature in degrees Fahrenheit.
- **wind**: Average wind speed (at 07:00 and 10:00) in miles per hour.

ethanol

*Engine exhaust fumes from burning ethanol*

**Description**

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

**Usage**

ethanol

**Format**

A data frame with 88 observations on the following 3 variables.

- **NOx**  Concentration of nitrogen oxides (NO and NO2) in micrograms/J.
- **C**  Compression ratio of the engine.
- **E**  Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

**Author(s)**

Documentation contributed by Kevin Wright.

            distance = .1,
            xlab = "C", ylab = "E", zlab = "NOx")
})
```

### histogram

**Histograms and Kernel Density Plots**

**Description**

Draw Histograms and Kernel Density Plots, possibly conditioned on other variables.

**Usage**

```r
histogram(x, data, ...)
densityplot(x, data, ...)
## S3 method for class 'formula':
histogram(x, data,
   allow.multiple, outer = TRUE,
   auto.key = FALSE,
   aspect = "fill",
   panel = lattice.getOption("panel.histogram"),
   prepanel, scales, strip, groups,
   xlab, xlim, ylab, ylim,
```

---

**histogram**

**Histograms and Kernel Density Plots**

**Description**

Draw Histograms and Kernel Density Plots, possibly conditioned on other variables.

**Usage**

```r
histogram(x, data, ...)
densityplot(x, data, ...)
## S3 method for class 'formula':
histogram(x, data,
   allow.multiple, outer = TRUE,
   auto.key = FALSE,
   aspect = "fill",
   panel = lattice.getOption("panel.histogram"),
   prepanel, scales, strip, groups,
   xlab, xlim, ylab, ylim,
```
Arguments

x

The object on which method dispatch is carried out.

For the formula method, a formula of the form ~ x | g1 + g2 + ... indicates that histograms or Kernel Density estimates of x should be produced conditioned on the levels of the (optional) variables g1, g2, .... x can be numeric (or factor for histogram), and each of g1, g2, ... must be either factors or shingles.
As a special case, the right hand side of the formula can contain more than one variable separated by a + sign. What happens in this case is described in details in the documentation for xyplot. Note that in either form, all the variables involved in the formula have to have same length.

For the numeric and factor methods, x replaces the x vector described above. Conditioning is not allowed in these cases.

**data**

For the formula method, an optional data frame in which variables are to be evaluated. Ignored with a warning in other cases.

**type**

Character string indicating type of histogram to be drawn. "percent" and "count" give relative frequency and frequency histograms, and can be misleading when breakpoints are not equally spaced. "density" produces a density scale histogram.

type defaults to "percent", except when the breakpoints are unequally spaced or breaks = NULL, when it defaults to "density".

**nint**

Number of bins. Applies only when breaks is unspecified or NULL in the call. Not applicable when the variable being plotted is a factor.

**endpoints**

vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when breaks is unspecified and the variable being plotted is not a factor. In do.breaks, this specifies the interval that is to be divided up.

**breaks**

usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of type that makes sense is density. When unspecified, the default is to use

\[
\text{breaks} = \text{seq}\_\text{len}(1 + \text{nlevels}(x)) - 0.5
\]

when x is a factor, and

\[
\text{breaks} = \text{do}\_\text{breaks}(\text{endpoints}, \text{nint})
\]

otherwise. Breakpoints calculated in such a manner are used in all panels.

Other values of breaks are possible, in which case they affect the display in each panel differently. A special value of breaks is NULL, in which case the number of bins is determined by nint and then breakpoints are chosen according to the value of equal.widths. Other valid values of breaks are those of the breaks argument in hist. This allows specification of breaks as an integer giving the number of bins (similar to nint), as a character string denoting a method, and as a function.

**equal.widths**

logical, relevant only when breaks=NULL. If TRUE, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (this would mean that the breakpoints will not be equally spaced).

**n**

number of points at which density is to be evaluated

**panel**

The function that uses the packet (subset of display variables) corresponding to a panel to create a display. Default panel functions are documented separately, and often have arguments that can be used to customize its display in various ways. Such arguments can usually be directly supplied to the high level function.

allow.multiple, outer, auto.key, aspect, prepanel, scales, strip, groups, xlab, xli

See xyplot.
bw, adjust, kernel, window, width, give.Rkern, from, to, cut, na.rm
arguments to density, passed on as appropriate

Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

histogram draws Conditional Histograms, while densityplot draws Conditional Kernel Density Plots. The density estimate in densityplot is actually calculated using the function density, and all arguments accepted by it can be passed (as ...) in the call to densityplot to control the output. See documentation of density for details. (Note: The default value of the argument n of density is changed to 50.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

do.breaks is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

Note

The form of the arguments accepted by the default panel function panel.histogram is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside histogram and passes only the breakpoints and the heights to the panel function, here the original variable x is passed along with the breakpoints. This allows plots as in the second example below.

### Functions to Interact with Lattice Plots

#### Description

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

#### Usage

```r
panel.identify(x, y = NULL,
    subscripts = seq_along(x),
    labels = subscripts,
    n = length(x), offset = 0.5,
    threshold = 18, ## in points, roughly 0.25 inches
    panel.args = trellis.panelArgs(),
    ...)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
    panel.args = trellis.panelArgs(),
    ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...

trellis.vpname(name = c("position", "split", "split.location", "toplevel", "panel", "strip", "strip.left", "legend", "main", "sub", "xlab", "ylab", "page"),
    column, row,
    side = c("left", "top", "right", "bottom", "inside"),
    clip.off = FALSE, prefix)
trellis.grobname(name, prefix)
trellis.focus(name, column, row, side, clip.off,
    highlight = interactive(), ...,
    guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ...

trellis.unfocus()
trellis.panelArgs(x, packet.number)
```
Arguments

\( x, y \) variables defining the contents of the panel. In the case of `trellis.panelArgs`, a "trellis" object.

\( n \) the number of points to identify by default (overridden by a right click)

\( \text{subscripts} \) an optional vector of integer indices associated with each point. See details below.

\( \text{labels} \) an optional vector of labels associated with each point. Defaults to \( \text{subscripts} \)

distribution, groups typical panel arguments of `panel.qqmath`. These will usually be obtained from `panel.args`

\( \text{offset} \) the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The `offset` specifies (in "char" units) how far from the identified point the labels should be printed.

\( \text{threshold} \) threshold in grid’s "points" units. Points further than these from the mouse click position are not considered

\( \text{panel.args} \) list that contains components names \( x \) (and usually \( y \)), to be used if \( x \) is missing. Typically, when called after `trellis.focus`, this would appropriately be the arguments passed to that panel.

\( \text{name} \) character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most that users might find interesting.

\( \text{trellis.vpname} \) and `trellis.focus` deal with viewport names only, and only accept the values explicitly listed above. `trellis.grobname` is meant to create names for grobs, and can currently accept any value.

If \( \text{name} \), as well as \( \text{column} \) and \( \text{row} \) is missing in a call to `trellis.focus`, the user can click inside a panel (or an associated strip) to focus on that panel.

\( \text{column, row} \) integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with `as.table=TRUE`

\( \text{guess} \) logical. If `TRUE`, and the display has only one panel, that panel will be automatically selected by a call to `trellis.focus`.

\( \text{side} \) character string, relevant only for legends (i.e. when `name="legend"`), indicating their position. Partial specification is allowed, as long as it is unambiguous.

\( \text{clip.off} \) logical, whether clipping should be off, relevant when `name` is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting `clip.off=FALSE` does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.

\( \text{prefix} \) character string acting as a prefix, meant to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the `prefix` argument in `print.trellis`. Users should not usually need to supply a value for this
interaction

argument (see note below), however, if supplied explicitly, this has to be a valid
R symbol name (briefly, it must start with a letter or a period followed by a
letter) and must not contain the grid path separator (currently ": ::")

highlight logical, whether the viewport being assigned focus should be highlighted. For
trellis.focus, the default is TRUE in interactive mode, and trellis.switchFocus
by default preserves the setting currently active.

packet.number integer, which panel to get data from. See packet.number for details on how
this is calculated

verbose whether details will be printed

... For panel.identify.qqmath, extra parameters are passed on to panel.identify.
For panel.identify, extra arguments are treated as graphical parameters
and are used for labelling. For trellis.focus and trellis.switchFocus,
these are used (in combination with lattice.options) for highlighting
the chosen viewport if so requested. Graphical parameters can be supplied for
panel.brush.splom.

Details

panel.identify is similar to identify. When called, it waits for the user to identify points
(in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure.
Although it is possible to call it as part of the panel function, it is more typical to use it to identify
points after plotting the whole object, in which case a call to trellis.focus first is necessary.

panel.brush.splom is meant for use with splom, and requires a panel to be chosen using
trellis.focus before it is called. Clicking on a point causes that and the corresponding projections
in other pairwise scatter plots to be highlighted.

panel.identify.qqmath is a specialized wrapper meant for use with the display produced
by qqmath.

One way in which panel.identify etc. are different from identify is in how it uses the
subscripts argument. In general, when one identifies points in a panel, one wants to identify
the origin in the data frame used to produce the plot, and not within that particular panel.
This information is available to the panel function, but only in certain situations. One way to en-
sure that subscripts is available is to specify subscripts = TRUE in the high level call
such as xyplot. If subscripts is not explicitly specified in the call to panel.identify,
but is available in panel.args, then those values will be used. Otherwise, they default to
seq_along(x). In either case, the final return value will be the subscripts that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports
which can then be accessed to modify the plot further. While full flexibility can only be obtained
by using grid functions directly, a few lattice functions are available for the more common tasks.

trellis.focus can be used to move to a particular panel or strip, identified by its position in
the array of panels. It can also be used to focus on the viewport corresponding to one of the labels
or a legend, though such usage would be less useful. The exact viewport is determined by the name
along with the other arguments, not all of which are relevant for all names. Note that when more
than one object is plotted on a page, trellis.focus will always go to the plot that was created
last. For more flexibility, use grid functions directly (see note below).
After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the 'current' viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current `row` and `column`. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```r
  trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the panel entry in `xyplot`) and not the position in the layout, because a layout determines the panel only after the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

**Value**

- `panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.
- `trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.
- `trellis.vpname` and `trellis.grobname` return character strings.
- `trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

**Note**

The viewports created by lattice is accessible to the user only up to a certain extent, as described above. In particular, `trellis.focus` can only be used to manipulate the last plot drawn. For full flexibility, use appropriate functions from the grid package directly.

For example, `current.vpTree`
can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` (with a non-default prefix argument) provides a portable way to access the appropriate viewports and grobs by name.

**Author(s)**

Deepayan Sarkar (Deepayan.Sarkar@R-project.org). Felix Andrews provided initial implementations of `panel.identify.qqmath` and support for focusing on panels interactively.

**Examples**

```r
## Not run:
xyplot(1:10 ~ 1:10)
trellis.focus("panel", 1, 1)
panel.identify()
## End(Not run)

xyplot(Petal.Length ~ Sepal.Length | Species, iris, layout = c(2, 2))
Sys.sleep(1)
trellis.focus("panel", 1, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 2, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 1, 2)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

## choosing loess smoothing parameter

p <- xyplot(dist ~ speed, cars)
panel.loessresid <-
  function(x = panel.args$x,
y = panel.args$y,
span, 
  panel.args = trellis.panelArgs())
{
fm <- loess(y ~ x, span = span)
xgrid <- do.breaks(current.panel.limits()$xlim, 50)
ygrid <- predict(fm, newdata = data.frame(x = xgrid))
panel.lines(xgrid, ygrid)
pred <- predict(fm)
## center residuals so that they fall inside panel
resids <- y - pred + mean(y)
fm.resid <- loess.smooth(x, resids, span = span)
##panel.points(x, resids, col = 1, pch = 4)
panel.lines(fm.resid, col = 1)

spans <- c(0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8)
update(p, index.cond = list(rep(1, length(spans))))
panel.locs <- trellis.currentLayout()
i <- 1
for (row in 1:nrow(panel.locs))
  for (column in 1:ncol(panel.locs))
    if (panel.locs[row, column] > 0)
      {
        trellis.focus("panel", row = row, column = column,
                       highlight = FALSE)
        panel.loessresid(span = spans[i])
grid::grid.text(paste("span = ", spans[i]),
                        x = 0.25,
                        y = 0.75,
                        default.units = "npc")
        trellis.unfocus()
        i <- i + 1
      }

---

**lattice.options**

*Low-level Options Controlling Behaviour of Lattice*

**Description**

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

**Usage**

lattice.options(...)
lattice.getOption(name)
Arguments

name character giving the name of a setting
... new options can be defined, or existing ones modified, using one or more arguments of the form name = value or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

Details

These functions are modeled on options andgetOption, and behave similarly for the most part. The components currently used are not documented here, but are fairly self-explanatory.

Value

lattice.getOption returns the value of a single component, whereas lattice.options always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by lattice.options. If called without any arguments, the full list is returned.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

Examples

str(lattice.options())
lattice.getOption("save.object")

latticeParseFormula

Parse Trellis formula

Description

this function is used by high level Lattice functions like xyplot to parse the formula argument and evaluate various components of the data.

Usage

latticeParseFormula(model, data, dimension = 2,
    subset = TRUE, groups = NULL,
    multiple, outer,
    subscripts, drop)
Arguments

model  
the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the dimension argument. The 2d formulas are of the form \( y \sim x | g_1 * \ldots * g_n \), and the 3d formulas are of the form \( z \sim x * y | g_1 * \ldots * g_n \). In the first form, \( y \) may be omitted. The conditioning variables \( g_1, \ldots, g_n \) can be omitted in either case.

data  
the environment/dataset where the variables in the formula are evaluated.

dimension  
dimension of the model, see above

subset  
index for choosing a subset of the data frame

groups  
the grouping variable, if present

multiple, outer
logicals, determining how a `+` in the \( y \) and \( x \) components of the formula are processed. See \texttt{xyplot} for details

subscripts  
logical, whether subscripts are to be calculated

drop  
logical or list, similar to the \texttt{drop.unused.levels} argument in \texttt{xyplot}, indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

Value

returns a list with several components, including \texttt{left}, \texttt{right}, \texttt{left.name}, \texttt{right.name}, \texttt{condition} for 2-D, and \texttt{left}, \texttt{right.x}, \texttt{right.y}, \texttt{left.name}, \texttt{right.x.name}, \texttt{right.y.name}, \texttt{condition} for 3-D. Other possible components are \texttt{groups}, \texttt{subscr}

---

level.colors  
A function to compute false colors representing a numeric or categorical variable

Description

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

Usage

\texttt{level.colors(x, at, col.regions, colors = TRUE, ...)}
level.colors

Arguments

x A numeric or factor variable
at A numeric variable of breakpoints where colors change
col.regions A specification of the colors to be used. This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors.
colors logical indicating whether colors should be computed and returned. If FALSE, only the indices representing which interval (among those defined by at) each value in x falls into is returned.
... Extra arguments, ignored.

Value

A vector of the same length as x. Depending on the colors argument, this could be either a vector of colors (in a form usable by R), or a vector of integer indices representing which interval the values of x fall in.

Author(s)

Deepayan Sarkar (deepayan.sarkar@r-project.org)

  with(quakes,
    level.colors(depth, at = do.breaks(range(depth), 30),
    col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
  strip = strip.custom(var.name = "Stations"),
  colours = depth.col,
  panel = function(x, y, colours, subscripts, ...) {
    panel.xyplot(x, y, pch = 21, col = "transparent",
    fill = colours[subscripts], ...)
  })
levelplot

Level Plots

Description

Draw Level Plots and Contour plots.

Usage

levelplot(x, data, ...)
contourplot(x, data, ...)

## S3 method for class 'formula':
levelplot(x,
data,
allow.multiple = is.null(groups) || outer,
outer = TRUE,
aspect = "fill",
panel = lattice.getOption("panel.levelplot"),
prepanel = NULL,
scales = list(),
strip = TRUE,
groups = NULL,
xlab,
xlim,
ylab,
ylim,
at,
cuts = 15,
pretty = FALSE,
region = TRUE,
drop.unused.levels = lattice.getOption("drop.unused.levels"),
...
,lattice.options = NULL,
default.scales = list(),
colorkey = region,
col.regions,
alpha.regions,
subset = TRUE)

## S3 method for class 'formula':
contourplot(x,
data,
panel = lattice.getOption("panel.contourplot"),
cuts = 7,
labels = TRUE,
contour = TRUE,
pretty = TRUE,
region = FALSE,
...)

## S3 method for class 'matrix':
levelplot(x, data = NULL, aspect = "iso", ...,
row.values, column.values)

## S3 method for class 'matrix':
contourplot(x, data = NULL, aspect = "iso", ...,
row.values, column.values)

Arguments

x for the formula method, a formula of the form z ~ x * y | g1 * g2 * ... where z is a numeric response, and x, y are numeric values evaluated on a rectangular grid. g1, g2, ... are optional conditional variables, and must be either factors or shingles if present. Calculations are based on the assumption that all x and y values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the x and y values need not be equally spaced.

Both levelplot and wireframe have methods for matrix objects, in which case x provides the z vector described above, while its rows and columns are interpreted as the x and y vectors respectively. This is similar to the form used in filled.contour and image.

data For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other cases.

row.values, column.values Optional vectors of values that define the grid when x is a matrix. row.values and column.values must have the same lengths as nrow(x) and ncol(x) respectively. By default, row and column numbers.

panel panel function used to create the display, as described in xyplot

aspect For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is aspect="fill", as described in xyplot.

at numeric vector giving breaks along the range of z. Contours (if any) will be drawn at these heights, and the regions in between would be colored using col.regions.

col.regions color vector to be used if regions is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than col.regions, the colors are recycled.
alpha.regions

numeric, specifying alpha transparency (works only on some devices)

colorkey

logical specifying whether a color key is to be drawn alongside the plot, or a list
describing the color key. The list may contain the following components:

**space**: location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right".

**x, y**: location, currently unused

col: vector of colors

**at**: numeric vector specifying where the colors change. must be of length 1 more than the col vector.

**labels**: a character vector for labelling the at values, or more commonly, a
list describing characteristics of the labels. This list may include components:
labels, at, cex, col, rot, font, fontface and fontfamily.

tick.number: approximate number of ticks.

corner: interacts with x, y; unimplemented

**width**: width of the key

**height**: length of key w.r.t side of plot.

contour

logical, whether to draw contour lines.

cuts

number of levels the range of z would be divided into

labels

typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for `panel.levelplot`, to which this argument is passed on unchanged. That help page also documents the `label.style` argument, which affects how the labels are rendered.

pretty

logical, whether to use pretty cut locations and labels

region

logical, whether regions between contour lines should be filled

allow.multiple, outer, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop
these arguments are described in the help page for `xyplot`.

... other arguments

Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

grid <- expand.grid(wtr.marginal)
grid[, "fit"] <- c(predict(ozo.m, grid))
contourplot(fit ~ wind * temperature | radiation, data = grid,
cuts = 10, region = TRUE,
xlab = "Wind Speed (mph)",
ylab = "Temperature (F)",
main = "Cube Root Ozone (cube root ppb)")
detach()
```

Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.
Usage

lplot.xy(xy, type, pch, lty, col, cex, lwd,
  font, fontfamily, fontface,
  col.line, alpha, fill,
  origin = 0, ...)

llines(x, ...)
lpoints(x, ...)
ltext(x, ...)

## Default S3 method:
llines(x, y = NULL, type = "l",
  col, alpha, lty, lwd, ...)
## Default S3 method:
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,
  font, fontfamily, fontface, cex, ...)
## Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
  col, alpha, cex, srt = 0,
  lineheight, font, fontfamily, fontface,
  adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ...)

lsegments(x0, y0, x1, y1, x2, y2,
  col, alpha, lty, lwd, ...)
lrect(xleft, ybottom, xright, ytop,
  x = (xleft + xright) / 2,
  y = (ybottom + ytop) / 2,
  width = xright - xleft,
  height = ytop - ybottom,
  col = "transparent",
  border = "black",
  lty = 1, lwd = 1, alpha = 1,
  just = "center",
  hjust = NULL, vjust = NULL,
  ...)
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
  angle = 30, code = 2, length = 0.25, unit = "inches",
  ends = switch(code, "first", "last", "both"),
  type = "open",
  col = add.line$col,
  alpha = add.line$alpha,
  lty = add.line$lty,
  lwd = add.line$lwd,
  fill = NULL, ...)
lpolygon(x, y = NULL,
  border = "black", col = "transparent",
  font, fontface, ...)

llines
panel.lines(...)  
panel.points(...)  
panel.segments(...)  
panel.text(...)  
panel.rect(...)  
panel.arrows(...)  
panel.polygon(...)  

Arguments

x, y, x0, y0, x1, y1, x2, y2, xy
locations. x2 and y2 are available for S compatibility.

length, unit determines extent of arrow head. length specifies the length in terms of unit,  
which can be any valid grid unit as long as it doesn’t need a data argument.  
unit defaults to inches, which is the only option in the base version of the  
function, arrows.

angle, code, type, labels, srt, adj, pos, offset  
arguments controlling behaviour. See respective base functions for details. For  
larrows and panel.larrows, type is either "open" or "closed", indicating  
the type of arrowhead.

ends serves the same function as code, using descriptive names rather than integer  
codes. If specified, this overrides code.

col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line, border  
graphical parameters. fill applies to points when pch is in 21:25 and  
specifies the fill color, similar to the bg argument in the base graphics function  
points. For devices that support alpha-transparency, a numeric argument  
alpha between 0 and 1 can controls transparency. Be careful with this, since  
for devices that do not support alpha-transparency, nothing will be drawn at all  
if this is set to anything other than 0. font and fontface are included in  
lpolygon only to ensure that they are not passed down (as gpar doesn’t like  
them).

origin for type="h" or type="H", the value to which lines drop down.

xleft, ybottom, xright, ytop  
see rect

width, height, just, hjust, vjust  
finer control over rectangles, see grid.rect

...  
extra arguments, passed on to lower level functions as appropriate.

Details

These functions are meant to be grid replacements of the corresponding base R graphics functions,  
to allow existing Trellis code to be used with minimal modification. The functions panel.* are  
essentially identical to the l* versions, are recommended for use in new code (as opposed to ported  
code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All  
these correspond to the default methods only.
Note

There is a new `type="h"` option wherever appropriate, which is similar to `type="h"`, but with horizontal lines.

**lset**

*Interface to modify Trellis Settings - Deprecated*

Description

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`.

Usage

```r
lset(theme = col.whitebg())
```

Arguments

- `theme` a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)
**make.groups**

*Grouped data from multiple vectors*

**Description**

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

**Usage**

`make.groups(...)`

**Arguments**

`...` one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

**Value**

When all the input arguments are vectors, a data frame with two columns

- all the vectors supplied, concatenated
- factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of `cbind` applied to them, along with an additional which column as described above.

Lattice

**Examples**

```r
sim.dat <-
  make.groups(uniform = runif(200),
              exponential = rexp(175),
              lognormal = rlnorm(150),
              normal = rnorm(125))
qqmath(~ data | which, sim.dat, scales = list(y = "free"))
```
Description

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

Usage

melanoma

Format

A data frame with 37 observations on the following 2 variables.

- year  Years 1936 to 1972.
- incidence  Rate of melanoma cancer per 100,000 population.

Note

This dataset is not related to the melanoma dataset in the boot package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per million, but this is not consistent with data found at the National Cancer Institute (http://www.nci.nih.gov).

Author(s)

Documentation contributed by Kevin Wright.

References

Examples

```r
# Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
data = melanoma,
    aspect = "xy",
    panel = function(x, y)
        panel.xyplot(x, y, type="o", pch = 16),
ylim = c(0, 6),
xlab = "Year",
ylab = "Incidence")
```
Fit One-way Model

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using rfs.

Usage

```r
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

Arguments

- `formula`: formula of the form `y ~ x` where `y` is the numeric response and `x` is the grouping factor.
- `data`: data frame in which the model is to be evaluated.
- `location`: function or numeric giving the location statistic to be used for centering the observations, e.g. `median`, 0 (to avoid centering).
- `spread`: function or numeric giving the spread statistic to be used for scaling the observations, e.g. `sd`, 1 (to avoid scaling).

Value

A list with components:

- `location`: vector of locations for each group.
- `spread`: vector of spreads for each group.
- `fitted.values`: vector of locations for each observation.
- `residuals`: residuals (`y - fitted.values`).
- `scaled.residuals`: residuals scaled by `spread` for their group.

packet.panel.default

**Associating Packets with Panels**

**Description**

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

**Usage**

```r
packet.panel.default(layout, condlevels, page, row, column,
skip, all.pages.skip = TRUE)
```

**Arguments**

- `layout`  
  the `layout` argument in high level functions, suitably standardized.
- `condlevels`  
  a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels
- `page, row, column`  
  the location of the panel in the coordinate system of pages, rows and columns.
- `skip`  
  the `skip` argument in high level functions
- `all.pages.skip`  
  whether `skip` should be replicated over all pages. If `FALSE`, `skip` will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

**Value**

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is `p`, then the `i`-th conditioning variable will have level `condlevels[[i]][p[i]]`.

```

panel.axis

Panel Function for Drawing Axis Ticks and Labels

Description

panel.axis is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. current.panel.limits can be used to retrieve a panel's x and y limits.

Usage

```
panel.axis(side = c("bottom", "left", "top", "right"),
at,
labels = TRUE,
draw.labels = TRUE,
check.overlap = FALSE,
outside = FALSE,
ticks = TRUE,
half = !outside,
which.half,
tck = as.numeric(ticks),
```
rot = if (is.logical(labels)) 0 else c(90, 0),
text.col, text.alpha, text.cex, text.font,
text.fontfamily, text.fontface,
line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")

Arguments

side character string indicating which side axes are to be drawn on. Partial specification is allowed.
at location of labels
labels the labels to go along with at. The labels can be a character vector or a vector of expressions. Alternatively, this can be a logical. If TRUE, the labels are derived from at, otherwise, labels are empty.
draw.labels logical indicating whether labels are to be drawn
check.overlap logical, whether to check for overlapping of labels. This also has the effect of removing at values that are 'too close' to the limits.
outside logical, whether to the labels draw outside the panel or inside. Note that outside=TRUE will only have a visible effect if clipping is disabled for the viewport (panel).
ticks logical, whether to draw the tickmarks
half logical, whether only half of scales will be drawn for each side
which.half character string, one of "lower" and "upper". Indicates which half is to be used for tick locations if half=TRUE. Defaults to whatever is suitable for splom
tck numeric scalar, multiplier for tick length. Can be negative.
rot rotation angles for labels in degrees. Can be a vector of length 2 for x- and y-axes respectively
text.col, text.alpha, text.cex, text.font, text.fontfamily, text.fontface, line.col, line.lty, line.lwd, line.alpha

Details

panel.axis can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in panel.pairs for splom, as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots ‘after the fact’ by adding axes.

Value

current.panel.limits returns a list with components xlim and ylim, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by unit, by default "native".
Description

Default panel function for `barchart`.

Usage

```
panel.barchart(x, y, box.ratio = 1,
horizontal = TRUE,
origin = NULL, reference = TRUE,
stack = FALSE,
groups = NULL,
col = if (is.null(groups)) plot.polygon$col else superpose.polygon$col,
border = if (is.null(groups)) plot.polygon$border else superpose.polygon$border,
lty = if (is.null(groups)) plot.polygon$lty else superpose.polygon$lty,
lwd = if (is.null(groups)) plot.polygon$lwd else superpose.polygon$lwd,
...)
```

Arguments

- **x**: Extent of Bars. By default, bars start at left of panel, unless `origin` is specified, in which case they start there.
- **y**: Horizontal location of bars, possibly factor.
- **box.ratio**: ratio of bar width to inter-bar space.
- **horizontal**: logical. If `FALSE`, the plot is ‘transposed’ in the sense that the behaviours of `x` and `y` are switched. `x` is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
- **origin**: the origin for the bars. For grouped displays with `stack = TRUE`, this argument is ignored and the origin set to 0. Otherwise, defaults to `NULL`, in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, `origin = 0` is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).
- **reference**: logical, whether a reference line is to be drawn at the origin.
stack logical, relevant when groups is non-null. If FALSE (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.

groups optional grouping variable
col, border, lty, lwd

... extra arguments will be accepted but ignored

Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level barchart call directly.

panel.bwplot Default Panel Function for bwplot

Description

This is the default panel function for bwplot.

Usage

panel.bwplot(x, y, box.ratio = 1,
             horizontal = TRUE,
             pch, col, cex,
             font, fontfamily, fontface,
             fill, varwidth = FALSE,
             ...,
             levels.fos,
             stats = boxplot.stats,
             coef = 1.5,
             do.out = TRUE)
Arguments

- **x, y**: numeric vector or factor. Boxplots drawn for each unique value of y (x) if `horizontal` is `TRUE` (`FALSE`)
- **box.ratio**: ratio of box height to inter box space
- **horizontal**: logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.
- **pch, col, cex, font, fontfamily, fontface**: graphical parameters controlling the dot. `pch="|"` is treated specially, by replacing the dot with a line (similar to `boxplot`)
- **fill**: color to fill the boxplot
- **varwidth**: logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.
- **stats**: a function, defaulting to `boxplot.stats`, that accepts a numeric vector and returns a list similar to the return value of `boxplot.stats`. The function must accept arguments `coef` and `do.out` even if they do not use them (a ... argument is good enough). This function is used to determine the box and whisker plot.
- **coef, do.out**: passed to `stats`
- **levels.fos**: numeric values corresponding to positions of the factor or shingle variable. For internal use.
- **...**: further arguments, ignored.

Details

Creates Box and Whisker plot of x for every level of y (or the reverse if `horizontal`=FALSE). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly. Unlike the traditional analog `boxplot`, notches are not implemented.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("box.rectangle" for the box, "box.umbrella" for the whiskers and "plot.symbol" for the outliers).

panel.cloud

Default Panel Function for cloud

Description

These are default panel functions controlling cloud and wireframe displays.

Usage

panel.cloud(x, y, subscripts, z, \\
groups = \text{NULL}, \\
perspective = \text{TRUE}, \\
distance = \text{if (perspective) 0.2 else 0}, \\
xlim, ylim, zlim, \\
panel.3d.cloud = "\text{panel.3dscatter}", \\
panel.3d.wireframe = "\text{panel.3dwire}", \\
screen = \text{list(z = 40, x = -60)}, \\
R.mat = \text{diag(4)}, \text{aspect} = \text{c(1, 1)}, \\
par.box = \text{NULL}, \\
xlab, ylab, zlab, \\
xlab.default, ylab.default, zlab.default, \\
scales.3d, \\
proportion = 0.6, \\
wireframe = \text{FALSE}, \\
scpos, \\
\ldots, \\
at)

panel.wireframe(\ldots)

panel.3dscatter(x, y, z, rot.mat, distance, \\
groups, type = "p", \\
xlim.scaled, ylim.scaled, zlim.scaled, \\
zero.scaled, \\
col, col.point, col.line, \\
lty, lwd, cex, pch, \\
cross, \ldots, subscripts)

panel.3dwire(x, y, z, rot.mat = \text{diag(4)}, distance,
shade = FALSE,
shade.colors.palette = trellis.par.get("shade.colors")$palette,
light.source = c(0, 0, 1000),
xlim.scaled,
ylim.scaled,
zlim.scaled,
col = if (shade) "transparent" else "black",
lty = 1, lwd = 1,
alpha,
col.groups = superpose.polygon$col,
polynum = 100,
..., drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha)

Arguments

x, y, z numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For `panel.cloud` these are essentially the same as the data passed to the high level plot (except if `formula` was a matrix, the appropriate x and y vectors are generated). By the time they are passed to `panel.3dscatter` and `panel.3dwire`, they have been appropriately subsetted (using `subscripts`) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).

Further, for `panel.3dwire`, x and y are shorter than z and represent the sorted locations defining a rectangular grid. Also in this case, z may be a matrix if the display is grouped, with each column representing one surface.

In `panel.cloud` (called from `wireframe`) and `panel.3dwire`, x, y and z could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.

subscripts index specifying which points to draw. The same x, y and z values (representing the whole data) are passed to `panel.cloud` for each panel. `subscripts` specifies the subset of rows to be used for the particular panel.

groups specification of a grouping variable, passed down from the high level functions.

perspective logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting `distance` to 0

distance numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is 1 / `distance`. This is described in a little more detail in the documentation for `cloud`.

screen A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.
initial rotation matrix in homogeneous coordinates, to be applied to the data before screen rotates the view further.

graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter box.3d

limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.

functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in cloud and wireframe. This function is called after the ‘back’ of the bounding box is drawn, but before the ‘front’ is drawn.

Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called xlim, ylim, zlim which give the bounding box ranges in the original data scale and xlim.scaled, ylim.scaled, zlim.scaled which give the bounding box ranges in the transformed scale.

More arguments can be considered on request.

dpects as in cloud

Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to cloud directly.

for internal use

for internal use

for internal use

list defining the scales

numeric scalar, gives the length of arrows as a proportion of the sides

A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of panel.cloud to see the details of this enumeration.)

logical, indicating whether this is a wireframe plot

logical, whether the facets will be colored by height, in a manner similar to levelplot. This is ignored if shade=TRUE.

deals with specification of colors when drape = TRUE in wireframe. at can be a numeric vector, col.regions a vector of colors, and alpha.regions a numeric scalar controlling transparency. The resulting behaviour is similar to levelplot, at giving the breakpoints along the z-axis where colors change, and the other two determining the colors of the facets that fall in between.

4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and R.mat arguments to panel.cloud
character vector, specifying type of cloud plot. Can include one or more
"p", "l", "h" or "b". "p" and "l" mean 'points' and 'lines' respectively,
and "b" means 'both'. "h" stands for 'histogram', and causes a line to be
drawn from each point to the X-Y plane (i.e., the plane representing $z = 0$), or
the lower (or upper) bounding box face, whichever is closer.

axis limits (after being scaled to the bounding box)

z-axis location (after being scaled to the bounding box) of the X-Y plane in the
original data scale, to which lines will be dropped (if within range) from each
point when type = "h"

logical, defaults to TRUE if pch = "+". panel.3dscatter can represent
each point by a 3d 'cross' of sorts (it’s much easier to understand looking at an
equivalent than from a description). This is different from the usual pch argument,
and reflects the depth of the points and the orientation of the axes. This
argument indicates whether this feature will be used.

This is useful for two reasons. It can be set to FALSE to use "+" as the plotting
character in the regular sense. It can also be used to force this feature in grouped
displays.

logical, indicating whether the surface is to be colored using an illumination
model with a single light source

a function (or the name of one) that is supposed to calculate the color of a facet
when shading is being used. Three pieces of information are available to the
function: first, the cosine of the angle between the incident light ray and the
normal to the surface (representing foreshortening); second, the cosine of half
the angle between the reflected ray and the viewing direction (useful for non-
Lambertian surfaces); and third, the scaled (average) height of that particular
facet with respect to the total plot z-axis limits.

All three numbers should be between 0 and 1. The shade.colors.palette function should return a valid color. The default function is obtained from the
trellis settings.

a 3-vector representing (in cartesian coordinates) the light source. This is rel-
relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis),
keeping in mind that all observations are bounded within the [-0.5, 0.5] cube

quadrilateral faces are drawn in batches of polynum at a time. Drawing too few
at a time increases the total number of calls to the underlying grid.polygon
function, which affects speed. Trying to draw too many at once may be unnec-
essarily memory intensive. This argument controls the trade-off.

colors for different groups

col, col.point, col.line, lty, lwd, cex, pch, alpha

... other parameters, passed down when appropriate

Details

These functions together are responsible for the content drawn inside each panel in cloud and
wireframe. panel.wireframe is a wrapper to panel.cloud, which does the actual work.
panel.densityplot is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether wireframe is TRUE, it calls either panel.3d.wireframe or panel.3d.cloud, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For cloud, the data is unstructured, and \( x, y \) and \( z \) are all passed to the panel.3d.cloud function. For wireframe, on the other hand, \( x \) and \( y \) are increasing vectors with unique values, defining a rectangular grid. \( z \) must be a matrix with \( \text{length}(x) \times \text{length}(y) \) rows, and as many columns as the number of groups.

panel.3dscatter is the default panel.3d.cloud function. It has a type argument similar to panel.xyplot, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

panel.3dwire is the default panel.3d.wireframe function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about polynum facets, and draws them all at once. This avoids the overhead of drawing grid.polygon repeatedly, speeding up the rendering considerably. If \( \text{shade} = \text{TRUE} \), these attempt to color the surface as being illuminated from a light source at \( \text{light.source} \). \( \text{palette.shade} \) is a simple function that provides the deafult shading colors.

Multiple surfaces are drawn if \( \text{groups} \) is non-null in the call to wireframe, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

panel.densityplot  Default Panel Function for densityplot

Description

This is the default panel function for densityplot.

Usage

panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
                  groups = NULL,
                  jitter.amount, type, ...)
Arguments

- **x**: data points for which density is to be estimated
- **darg**: list of arguments to be passed to the `density` function. Typically, this should be a list with zero or more of the following components: `bw`, `adjust`, `kernel`, `window`, `width`, `give.Rkern`, `n`, `from`, `to`, `cut`, `na.rm` (see `density` for details)
- **plot.points**: logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case `panel.rug` is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points.
- **ref**: logical, whether to draw x-axis
- **groups**: an optional grouping variable. If present, `panel.superpose` will be used instead to display each subgroup
- **jitter.amount**: when `plot.points`="jitter", the value to use as the amount argument to `jitter`.
- **type**: type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a type argument, if specified, from affecting the density curve.
- **...**: extra graphical parameters

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

- `densityplot.jitter`

panel.dotplot  
Default Panel Function for dotplot

Description

Default panel function for `dotplot`.

Usage

```r
panel.dotplot(x, y, horizontal = TRUE, pch, col, lty, lwd, col.line, levels.fos, groups = NULL, ...
)```
Arguments

\texttt{x, y} \hspace{1cm} \text{variables to be plotted in the panel. Typically y is the ‘factor’}

\texttt{horizontal} \hspace{1cm} \text{logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of \texttt{bwplot} for a fuller explanation.}

\texttt{pch, col, lty, lwd, col.line} \hspace{1cm} \text{graphical parameters}

\texttt{levels.fos} \hspace{1cm} \text{locations where reference lines will be drawn}

\texttt{groups} \hspace{1cm} \text{grouping variable (affects graphical parameters)}

\texttt{...} \hspace{1cm} \text{extra parameters, passed to \texttt{panel.xyplot} which is responsible for drawing the foreground points (\texttt{panel.dotplot} only draws the background reference lines).}

Details

Creates (possibly grouped) Dotplot of \texttt{x} against \texttt{y} or vice versa

dotplot

\begin{center}
\textbf{panel.functions} \hspace{1cm} \textit{Useful Panel Functions}
\end{center}

Description

These are predefined panel functions available in lattice for use in constructing new panel functions (usually on-the-fly).

Usage

\begin{verbatim}
panel.abline(a = NULL, b = 0,
             h = NULL, v = NULL,
             reg = NULL, coef = NULL,
             col, col.line, lty, lwd, alpha, type,
             ...)  

panel.curve(expr, from, to, n = 101,
             curve.type = "l",
             col, lty, lwd, type,
             ...)
\end{verbatim}
Arguments

x, y  variables defining the contents of the panel

a, b  Coefficients of the line to be added by `panel.abline`. a can be a vector of length 2, representing the coefficients of the line to be added, in which case b should be missing. a can also be an appropriate 'regression' object, i.e., an object which has a coef method that returns a length 2 numeric vector. The corresponding line will be plotted. The reg argument will override a if specified.

coeff  Coefficients of the line to be added as a length 2 vector

reg  A regression object. The corresponding fitted line will be drawn

h, v  For `panel.abline`, these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For `panel.grid`, these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. h=-1 and v=-1 are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using pretty, which is also how the label positions are chosen in the most common cases (but not for factor or date-time variables, for instance).
h and v can be negative numbers other than -1, in which case -h and -v (as appropriate) is supplied as the n argument to pretty.

expr
equation as a function of x or a function to plot as a curve

n
the number of points to use for drawing the curve

regular
logical indicating whether the ‘rug’ is to be drawn on the regular side (left / bottom) or not (right / top)

start, end
endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of regular, and cover 3% of the panel width and height

x.units, y.units
character vector, replicated to be of length two. Specifies the (grid) units associated with start and end above. x.units and y.units are for the rug on the x-axis and y-axis respectively (and thus are associated with start and end values on the y and x scales respectively).

from, to
optional lower and upper x-limits of curve. If missing, limits of current panel are used

curve.type
type of curve ("p" for points, etc), passed to llines

col, col.line, lty, lwd, alpha, border
graphical parameters

type
usually ignored. This is present only to make sure an explicitly specified type argument (perhaps meant for another function) doesn’t affect the display.

span, degree, family, evaluation
arguments to loess.smooth, for which panel.loess is essentially a wrapper

fun
the function that will be applied to the subset of x(y) determined by the unique values of y(x)

horizontal
logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.

dmath
A vectorized function that produces density values given a numeric vector named x, e.g., dnorm

args
list giving additional arguments to be passed to dmath

...
graphical parameters can be supplied. see function definition for details. Color can usually be specified by col, col.line and col.symbol, the last two overriding the first for lines and points respectively.

Details

panel.abline adds a line of the form y=a+bx or vertical and/or horizontal lines. Graphical parameters are obtained from reference.line for panel.grid, and add.line for the others (can be set using trellis.par.set)

panel.curve adds a curve, similar to what curve does with add = TRUE. Graphical parameters for the line are obtained from the add.line setting.

panel.average treats one of x and y as a factor (according to the value of horizontal), calculates fun applied to the subsets of the other variable determined by each unique value of
the factor, and joins them by a line. Can be used in conjunction with panel.xyplot and more commonly with panel.superpose to produce interaction plots. See xyplot documentation for an example. panel.linejoin is an alias for panel.average retained for back-compatibility and may go away in future.

panel.mathdensity plots a (usually theoretical) probability density function. This can be useful in conjunction with histogram and densityplot to visually estimate goodness of fit (note, however, that qqmath is more suitable for this).

panel.rug adds a rug representation of the (marginal) data to the panel, much like rug.

panel.lmline(x, y) is equivalent to panel.abline(lm(y~x)).

panel.histogram Default Panel Function for histogram

Description

This is the default panel function for histogram.

Usage

panel.histogram(x, 
    breaks, 
    equal.widths = TRUE, 
    type = "density", 
    nint = round(log2(length(x)) + 1), 
    alpha, col, border, lty, lwd, 
    ...) 

Arguments

x
breaks
equal.widths
type
nint
alpha, col, border, lty, lwd

The data points for which the histogram is to be drawn
The breakpoints for the histogram
logical used when breaks==NULL
Type of histogram, possible values being "percent", "density" and "count"
Number of bins for the histogram
graphical parameters for bars; defaults are obtained from the plotpolygon settings.
other arguments, passed to hist when deemed appropriate

histogram

panel.levelplot  Default Panel Function for levelplot

Description

This is the default panel function for levelplot.

Usage

panel.levelplot(x, y, z, subscripts, at = pretty(z), shrink, labels = NULL, label.style = c("mixed", "flat", "align"), contour = FALSE, region = TRUE, col = add.line$col, lty = add.line$lty, lwd = add.line$lwd, ...) 

panel.contourplot(...) 

Arguments

x, y, z  variables defining the plot
subscripts  integer vector indicating what subset of x, y and z to draw
at  numeric vector specifying breakpoints for change in colors
shrink  either a numeric vector of length 2 (meant to work as both x and y components), or a list with components x and y which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the z-value. The specification can be made separately for widths (x) and heights (y). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of z).
labels  either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the at values. Alternatively, labels can be a list with the following components:
panel.number

labels: a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.
col, cex, alpha: graphical parameters for label texts
fontfamily, fontface, font: font used for the labels
label.style controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.
contour logical, specifying whether contour lines should be drawn
region logical, specifying whether inter-contour regions should be filled with the appropriate color
col, lty, lwd graphical parameters for contour lines
... extra parameters
col.regions a vector of colors used if region=TRUE. Usually a subset of the colors are used, the exact number being one more than the length of at. These are chosen to be roughly equally spaced along col.regions. In the unusual case when col.regions is not longer than at, it is repeated to be as long as necessary.
alpha.regions numeric scalar controlling transparency of facets

Details
The same function is used for both levelplot and contourplot (which differ only in default values of some arguments). panel.contourplot is a simple wrapper to panel.levelplot.
When contour=TRUE, the contourLines function is used to calculate the contour lines.

levelplot, contourLines

Description
Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the panel, strip and axis functions.
Usage

current.row()
current.column()
panel.number()
packet.number()
which.packet()

trellis.currentLayout(which = c("packet", "panel"))

Arguments

which  whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).

Value

trellis.currentLayout returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. current.row and current.column return integer indices specifying which row and column in the layout are currently active. panel.number returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). packet.number gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. which.packet returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called panel.number and packet.number that were made available to panel and strip. If you have written such functions, it should be enough to replace instances of panel.number and packet.number by the corresponding function calls. You should also remove panel.number and packet.number from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

panel.pairs

Default Superpanel Function for splom

Description

This is the default superpanel function for splom.

Usage

panel.pairs(z,
    panel = lattice.getOption("panel.splom"),
    lower.panel = panel,
    upper.panel = panel,
    diag.panel = "diag.panel.splom",
    as.matrix = FALSE,
    groups = NULL,
    panel.subscripts,
    subscripts,
    pscales = 5,
    prepanel.limits = function(x) if (is.factor(x)) levels(x) else extend.limits(range(as.numeric(x), finite = TRUE)),
    varname.col, varname.cex, varname.font, varname.fontfamily, varname.fontface,
    axis.text.col, axis.text.cex, axis.text.font, axis.text.fontfamily, axis.text.fontface,
    axis.line.col, axis.line.lty, axis.line.lwd, axis.line.alpha, axis.line.tck,
    ...
)

diag.panel.splom(x = NULL,
    varname = NULL, limits, at = NULL, lab = NULL,
    draw = TRUE, varname.col, varname.cex, varname.lineheight, varname.font, varname.fontfamily, varname.fontface,
    axis.text.col, axis.text.alpha, axis.text.cex, axis.text.font, axis.text.fontfamily, axis.text.fontface,
    axis.line.col, axis.line.alpha, axis.line.lty, axis.line.lwd, axis.line.tck,
    ...
)

Arguments

z

The data frame used for the plot.
The panel function used to display each pair of variables. If specified, `lower.panel` and `upper.panel` are used for panels below and above the diagonal respectively.

The panel function used for the diagonals. See arguments to `diag.panel.splom` to know what arguments this function is passed when called.

logical. If `TRUE`, the layout of the panels will have origin on the top left instead of bottom left (similar to `pairs`). This is in essence the same functionality as provided by `as.table` for the panel layout.

Grouping variable, if any

logical specifying whether the panel function accepts an argument named `subscripts`.

The indices of the rows of `z` that are to be displayed in this (super)panel.

Controls axis labels, passed down from `splom`. If `pscales` is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If `pscales` is a list, it should have one component for each column in `z`, each of which itself a list with the following valid components:

- `at`: a numeric vector specifying tick locations
- `labels`: character vector labels to go with `at`
- `limits`: numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors)

These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use `pscales=0` to suppress the axes entirely.

The ‘regular’ high level lattice plots such as `xyplot` use the `prepanel` function for deciding on axis limits from data. This function serves a similar function, and works on a per-variable basis, by calculating the limits, which can be overridden by the corresponding `limits` component in the `pscales` list.

data vector corresponding to that row / column (which will be the same for diagonal ‘panels’).

(scalar) character string or expression that is to be written centred within the panel

numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)

locations of tick marks

optional labels for tick marks

logical, specifying whether to draw the tick marks and labels. If `FALSE`, only variable names are written

graphical parameters for the variable name in each diagonal panel

graphical parameters for axis tick marks and labels
panel.parallel

axis.line.tck
length of tick marks in diagonal panels

... extra arguments passed on to panel, lower.panel, upper.panel and diag.panel from panel.pairs. Currently ignored by diag.panel.splom.

Details

panel.pairs is the function that is actually passed in as the panel function in a trellis object produced by splom (taking the panel function as its argument).

Note that the axis labeling does not support date-time classes at present.

splom

panel.parallel 

Default Panel Function for parallel

Description

This is the default panel function for parallel.

Usage

panel.parallel(x, y, z, subscripts,
            groups = NULL,
            col, lwd, lty, alpha,
            common.scale = FALSE,
            lower,
            upper,
            ...)

Arguments

x, y dummy variables, ignored.

z The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.

subscripts The indices of the rows of z that are to be displayed in this panel.

groups An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of z in the same group share parameters).
col, lwd, lty, alpha

graphical parameters (defaults to the settings for superpose.line). If groups is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame z.

common.scale logical, whether a common scale should be used columns of z. Defaults to FALSE, in which case the horizontal range for each column is different (as determined by lower and upper).

lower, upper numeric vectors replicated to be as long as the number of columns in z. Determines the lower and upper bounds to be used for scaling the corresponding columns of z after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.

... other arguments (ignored)

Details

Difficult to describe. See example for parallel

panel.qqmath Default Panel and Prepanel Function for qqmath

Description

This is the default panel function for qqmath.

Usage

panel.qqmath(x, f.value = NULL,
            distribution = qnorm,
            qtype = 7,
            groups = NULL, ...)

Arguments

x vector (typically numeric, coerced if not) of data values to be used in the panel.
f.value, distribution

Defines how quantiles are calculated. See qqmath for details.

qtype The type argument to be used in quantile
An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.

... further arguments, often graphical parameters.

Details

Creates a Q-Q plot of the data and the theoretical distribution given by distribution. Note that most of the arguments controlling the display can be supplied directly to the high-level qqmath call.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

See Also

qqmath

Description

Useful panel function with qqmath. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

Usage

panel.qqmathline(x, y = x,
          distribution = qnorm,
          p = c(0.25, 0.75),
          qtype = 7,
          groups = NULL,
          ...)

Arguments

x

The original sample, possibly reduced to a fewer number of quantiles, as determined by the f.value argument to qqmath

y

an alias for x for backwards compatibility

distribution

quantile function for reference theoretical distribution.

p

numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.

qtype

the type of quantile computation used in quantile

groups

optional grouping variable. If non-null, a line will be drawn for each group.

... other arguments.
panel.stripplot

Default Panel Function for stripplot

Description

This is the default panel function for stripplot. Also see panel.superpose

Usage

panel.stripplot(x, y, jitter.data = FALSE,
    factor = 0.5, amount = NULL,
    horizontal = TRUE, groups = NULL,
    ...) # Arguments

Arguments

x, y coordinates of points to be plotted
jitter.data whether points should be jittered to avoid overplotting.
factor, amount amount of jittering, see jitter
horizontal logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of
x and y are switched. x is now the ‘factor’. Interpretation of other arguments
change accordingly. See documentation of bwplot for a fuller explanation.
groups optional grouping variable
... additional arguments, passed on to panel.xyplot

Details

Creates stripplot (one dimensional scatterplot) of x for each level of y (or vice versa, depending on
the value of horizontal)

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

stripplot, jitter
panel.superpose  Panel Function for Display Marked by groups

Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The \( x \) (and \( y \) where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

Usage

```r
panel.superpose(x, y = NULL, subscripts, groups,
    panel.groups = "panel.xyplot",
    col, col.line, col.symbol,
    pch, cex, fill, font,
    fontface, fontfamily,
    lty, lwd, alpha,
    type = "p",
    ...
    distribute.type = FALSE)

panel.superpose.2(..., distribute.type = TRUE)
```

Arguments

- **x, y** coordinates of the points to be displayed
- **panel.groups** the panel function to be used for each group of points. Defaults to `panel.xyplot` (behaviour in S).
  - To be able to distinguish between different levels of the originating group inside `panel.groups`, it will be supplied a special argument called `group.number` which will hold the numeric code corresponding to the current level of `groups`. No special care needs to be taken when writing a `panel.groups` function if this feature is not used.
- **subscripts** subscripts giving indices in original data frame
- **groups** a grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of `groups`. The default graphical parameters are obtained from `superpose.symbol` and `superpose.line` using `trellis.par.get` wherever appropriate.
- **type** usually a character vector specifying what should be drawn for each group, passed on to the `panel.groups` function, which must know what to do with it. By default, this is `panel.xyplot`, whose help page describes the admissible values.
  - The functions `panel.superpose` and `panel.superpose.2` differ only in the default value of `distribute.type`, which controls the way the `type` argument is interpreted. If `distribute.type = FALSE`, then the interpretation is the same as for `panel.xyplot` for each of the unique groups. In
other words, if \texttt{type} is a vector, all the individual components are honoured concurrently. If \texttt{distribute.type = TRUE}, \texttt{type} is replicated to be as long as the number of unique values in \texttt{groups}, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying \texttt{type} as a list, each component being the desired \texttt{type} vector for the corresponding group.

If \texttt{distribute.type = FALSE}, any occurrence of "g" in \texttt{type} causes a grid to be drawn, and all such occurrences are removed before \texttt{type} is passed on to \texttt{panel.groups}.

\texttt{col, col.line, col.symbol, pch, cex, fill, font, fontface, fontfamily, lty, lwd, alpha}

graphical parameters, replicated to be as long as the number of groups. These are eventually passed down to \texttt{panel.groups}, but as scalars rather than vectors. When \texttt{panel.groups} is called for the \texttt{i}-th level of \texttt{groups}, the corresponding element of each graphical parameter is passed to it.

\texttt{...}

Extra arguments. Passed down to \texttt{panel.superpose} from \texttt{panel.superpose.2}, and to \texttt{panel.groups} from \texttt{panel.superpose}.

distribute.type

logical controlling interpretation of the \texttt{type} argument.

Details

\texttt{panel.superpose} and \texttt{panel.superpose.2} differ essentially in how \texttt{type} is interpreted by default. The default behaviour in \texttt{panel.superpose} is the opposite of that in S, which is the same as that of \texttt{panel.superpose.2}.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org) (\texttt{panel.superpose.2} originally contributed by Neil Klepeis)

See Also

Different functions when used as \texttt{panel.groups} gives different types of plots, for example \texttt{panel.xyplot}, \texttt{panel.dotplot} and \texttt{panel.linejoin} (This can be used to produce interaction plots).

See \texttt{Lattice} for an overview of the package.
Usage

```r
panel.violin(x, y, box.ratio = 1, horizontal = TRUE,
    alpha, border, lty, lwd, col,
    varwidth = FALSE,
    bw, adjust, kernel, window,
    width, n = 50, from, to, cut,
    na.rm, ...)
```

Arguments

- **x, y**
  - numeric vector or factor. Violin plots are drawn for each unique value of `y (x)` if `horizontal` is `TRUE (FALSE)`
- **box.ratio**
  - ratio of height of a violin and inter violin space
- **horizontal**
  - logical. If `FALSE`, the plot is 'transposed' in the sense that the behaviours of `x` and `y` are switched. `x` is now the 'factor'. See documentation of `bwplot` for a fuller explanation.
- **alpha, border, lty, lwd, col**
  - graphical parameters controlling the violin. Defaults are taken from the "plot.polygon" settings.
- **varwidth**
  - logical. If `FALSE`, the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by `box.ratio`). If `TRUE`, densities across violins will have comparable scale.
- **bw, adjust, kernel, window, width, n, from, to, cut, na.rm**
  - arguments to `density`, passed on as appropriate
- **...**
  - arguments passed on to `density`.

Details

Creates Violin plot of `x` for every level of `y`. Note that most arguments controlling the display can be supplied to the high-level (typically `bwplot`) call directly.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

See Also

- `bwplot`, `density`

Examples

```r
bwplot(voice.part ~ height, singer,
   panel = function(..., box.ratio) {
     panel.violin(..., col = "transparent",
                varwidth = FALSE, box.ratio = box.ratio)
```
panel.xyplot

Default Panel Function for xyplot

Description

This is the default panel function for xyplot. Also see panel.superpose. The default panel functions for splom and qq are essentially the same function.

Usage

```r
panel.xyplot(x, y, type = "p",
groups = NULL,
  pch, col, col.line, col.symbol,
  font, fontfamily, fontface,
  lty, cex, fill, lwd,
  horizontal = FALSE, ...,
  jitter.x = FALSE, jitter.y = FALSE,
  factor = 0.5, amount = NULL)
```

panel.splom(...)

panel.qq(...)

Arguments

- **x, y**
  variables to be plotted in the scatterplot

- **type**
  character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth". If type has more than one element, an attempt is made to combine the effect of each of the components. The behaviour if any of the first six are included in type is similar to the effect of type in plot (type "b" is actually the same as "o"). "r" adds a regression line (same as panel.lmline, except for default graphical parameters), and "smooth" adds a lowess fit (same as panel.loess). "g" adds a reference grid using panel.grid in the background. "a" has the effect of calling panel.linejoin, which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of horizontal. See example(xyplot) and demo(lattice) for examples.

- **groups**
  an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup

- **col, col.line, col.symbol**
  default colours are obtained from plot.symbol and plot.line using trellis.par.get.

- **font, fontface, fontfamily**
  font used when pch is a character
pch, lty, cex, lwd, fill

other graphical parameters. fill serves the purpose of bg in points for
certain values of pch

extra arguments, if any, for panel.xyplot. In most cases panel.xyplot
ignores these. For types "r" and "smooth", these are passed on to panel.lmline
and panel.loess respectively.

horizontal logical. Controls orientation for certain type's, e.g. one of "h", "s" or "S"
jitter.x, jitter.y

logical, whether the data should be jittered before being plotted.

factor, amount

controls amount of jittering.

Details

Creates scatterplot of x and y, with various modifications possible via the type argument. panel.qq
draws a 45 degree line before calling panel.xyplot.

Note that most of the arguments controlling the display can be supplied directly to the high-level
(e.g. xyplot) call.

  grid::grid.rect()
prepanel.default  Default Prepanel Functions

Description

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

Usage

prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance, xlim, ylim, zlim,
  screen = list(z = 40, x = -60),
  R.mat = diag(4),
  aspect = c(1, 1), panel.aspect = 1,
  ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
  groups, subscripts, ...)
prepanel.default.densityplot(x, darg, groups, subscripts, ...)
prepanel.default.parallel(x, y, z, ...)
prepanel.default.splom(z, ...)

Arguments

x, y  x and y values, numeric or factor
horizontal  logical, applicable when one of the variables is to be treated as categorical (factor or shingle)
nlevels  number of levels of such a categorical variable.
origin, stack
  for barcharts or the type="h" plot type
breaks, equal.widths, type, nint
  details of histogram calculations. type has a different meaning in prepanel.default.xyplot
  (see panel.xyplot)
groups, subscripts
  See xyplot. Whenever appropriate, calculations are done separately for each
group and then combined.
perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom
  see panel.cloud
f.value, distribution
  see panel.qqmath
darg
  list of arguments passed to density
z
  see panel.parallel and panel.pairs
qtype
  type of quantile
...
  other arguments, usually ignored

Value

A list with components xlim, ylim, dx and dy, and possibly xat and yat, the first two being
used to calculate panel axes limits, the last two for banking computations. The form of these
components are described in the help page for xyplot.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

See Also

xyplot, banking, Lattice. See documentation of corresponding panel functions for more
details about the arguments.
print.trellis

Arguments

x, y x and y values, numeric or factor
distribution quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in qqmath.
qtype type of quantile
p numeric vector of length two, representing probabilities. If used with aspect="xy", the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible.
span, degree, family, evaluation arguments controlling the underlying loess smooth
groups, subscripts See xyplot. Whenever appropriate, calculations are done separately for each group and then combined.
... other arguments

Value

usually a list with components xlim, ylim, dx and dy, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under xyplot. There are also several prepanel functions that serve as the default for high level functions, see prepanel.default.xyplot

print.trellis Plot and Summarize Trellis Objects

Description

The print and plot methods produce a graph from a "trellis" object. The print method is necessary for automatic plotting. plot method is essentially an alias, provided for convenience. The summary method gives a textual summary of the object. dim and dimnames describe the cross-tabulation induced by conditioning. panel.error is the default handler used when an error occurs while executing the panel function.
print.trellis

Usage

## S3 method for class 'trellis':
plot(x, position, split,
    more = FALSE, newpage = TRUE,
    packet.panel = packet.panel.default,
    draw.in = NULL,
    panel.height = lattice.getOption("layout.heights")$panel,
    panel.width = lattice.getOption("layout.widths")$panel,
    save.object = lattice.getOption("save.object"),
    panel.error = lattice.getOption("panel.error"),
    prefix,
    ...)

## S3 method for class 'trellis':
print(x, ...)

## S3 method for class 'trellis':
summary(object, ...)

## S3 method for class 'trellis':
dim(x)

## S3 method for class 'trellis':
dimnames(x)

panel.error(e)

Arguments

x, object  an object of class "trellis"

position  a vector of 4 numbers, typically c(xmin, ymin, xmax, ymax) that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of x is to be positioned. The coordinate system for this rectangle is [0-1] in both the x and y directions.

split  a vector of 4 integers, c(x,y,nx,ny) . that says to position the current plot at the x,y position in a regular array of nx by ny plots. (Note: this has origin at top left)

more  A logical specifying whether more plots will follow on this page.

newpage  A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).

packet.panel  a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default,
namely the function `packet.panel.default`, whose help page details the arguments supplied to whichever function is specified as the `packet.panel` argument.

**draw.in**
An optional (grid) viewport (used as the `name` argument in `downViewport`) in which the plot is to be drawn. If specified, the `newpage` argument is ignored. This feature is not well-tested.

**panel.width, panel.height**
lists with 2 components, that should be valid `x` and `units` arguments to `unit()` (the `data` argument cannot be specified currently, but can be considered for addition if needed). The resulting `unit` object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.

Note that this option should not be used in conjunction with non-default values of the `aspect` argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).

**save.object**
logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel’s data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the `update` method on the current plot, even if it was not assigned to a variable explicitly. For more details, see `trellis.focus`.

**panel.error**
a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using `tryCatch`) and supplied as the only argument to `panel.error`. The default behaviour (implemented as the the `panel.error` function) is to print the corresponding error message in the panel and continue. To stop execution on error, use `panel.error = stop`.

**prefix**
character string used as a prefix in viewport and grob names, used to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (which is one more than the number of plots that have been drawn on the page before the current plot). If supplied explicitly, this has to be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently `"::"`).

e
an error condition caught by `tryCatch`

... extra arguments, ignored by the `print` method. All arguments to the `plot` method are passed on to the `print` method.

**Details**
This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`. 
When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see `trellis.focus`.

**Note**

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

**Examples**

```r
p11 <- histogram(~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~ height, data = singer, xlab = "Height")

## simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))

## Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

## Using seekViewport
## repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
       layout = c(3, 2),
       panel = function(x, y, 
        {
           panel.xyplot(x, y, 
           fm <- lm(y ~ poly(x, panel.number()))
           llines(x, predict(fm))
         }
       )
```
## Not run:

```r
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:

ltext(grid::grid.locator(), lab = "linear")
## End(Not run)
```

```r
grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")
```

```r
grid::seekViewport(trellis.vpname("panel", 2, 1))
grid::grid.text("quadratic")
```

```r
grid::seekViewport(trellis.vpname("panel", 3, 1))

**qq**

*Quantile-Quantile Plots of Two Samples*

### Description

Quantile-Quantile plots for comparing two Distributions

### Usage

```r
qq(x, data, ...)  
```

## S3 method for class 'formula'

```r
qq(x, data, aspect = "fill",  
    panel = lattice.getOption("panel.qq"),  
    prepanel, scales, strip,  
    groups, xlab, xlim, ylab, ylim, f.value = NULL,  
    drop.unused.levels = lattice.getOption("drop.unused.levels"),  
    ...,  
    lattice.options = NULL,  
    qtype = 7,  
    default.scales = list(),  
    subscripts,  
    subset)
```
Arguments

x
The object on which method dispatch is carried out.
For the formula method, a formula of the form \( y \sim x \mid g1 \times g2 \times \ldots \),
where \( x \) must be a numeric, and \( y \) can be a factor, shingle, character or numeric
vector, with the restriction that there must be exactly two levels of \( y \), which
divide the values of \( x \) into two groups. Quantiles for these groups will be plotted
along the two axes.

data
For the formula methods, an optional data frame in which variables in the
formula (as well as groups and subset, if any) are to be evaluated.
f.value
optional numeric vector of probabilities, quantiles corresponding to which should
be plotted. Can also be a function of a single integer (representing sample size)
that returns such a numeric vector. The typical value for this argument is the
function `ppoints`, which is also the S-PLUS default. If specified, the probabil-
ities generated by this function is used for the plotted quantiles, using the
`quantile` function.

f.value defaults to NULL, which is equivalent to using `function(n) ppoints(n,
a = 1)`. This has the effect of including the minimum and maximum data val-
ues in the computed quantiles. This is similar to what happens for `qqplot` but
different from the default `qq` behaviour in S-PLUS.
For large data, this argument can be useful in plotting a smaller set of quantiles,
which is usually enough to capture the pattern.

panel
The function that uses the packet (subset of display variables) corresponding to a
panel to create a display. Default panel functions are documented separately, and
often have arguments that can be used to customize its display in various ways.
Such arguments can usually be directly supplied to the high level function.

qtype
type argument for the `quantile`

Details

`qq` produces a Q-Q plot of two samples. The default behaviour of `qq` is different from the corre-
sponding S-PLUS function. See the entry for `f.value` for specifics.
This and all other high level Trellis functions have several arguments in common. These are ex-
tensively documented only in the help page for `xyplot`, which should be consulted to learn more
detailed usage.

Value

An object of class "trellis". The `update` method can be used to update components of the
object and the `print` method (usually called by default) will plot it on an appropriate plotting
device.

Examples

```r
qq(voice.part ~ height, aspect = 1, data = singer,
   subset = (voice.part == "Bass 2" | voice.part == "Tenor 1"))
```

### Q-Q Plot with Theoretical Distribution

**Description**

Quantile-Quantile plot of a sample and a theoretical distribution

**Usage**

```r
qqmath(x, data, ...)
```

#### S3 method for class 'formula':

```r
qqmath(x,
   data,
   allow.multiple = is.null(groups) || outer,
   outer = !is.null(groups),
   distribution = qnorm,
   f.value = NULL,
   auto.key = FALSE,
   aspect = "fill",
   panel = lattice.getOption("panel.qqmath"),
   prepanel = NULL,
   scales, strip, groups,
   xlab, xlim, ylab, ylim,
   drop.unused.levels = lattice.getOption("drop.unused.levels"),
   ...
   lattice.options = NULL,
   default.scales = list(),
   subscripts,
   subset)
```

#### S3 method for class 'numeric':

```r
qqmath(x, data = NULL, ylab, ...)
```

**Arguments**

- `x`  
  The object on which method dispatch is carried out.  
  For the "formula" method, a formula of the form `~ x | g1 * g2 * ...`, where `x` must be a numeric. For the "numeric" method, a numeric vector.
For the formula method, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other methods.

distribution a quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles. Possible values are qnorm, qunif etc. Distributions with other required arguments need to be passed in as user defined functions.

f.value optional numeric vector of probabilities, quantiles corresponding to which should be plotted. Can also be a function of a single integer (representing sample size) that returns such a numeric vector. The typical value for this argument is the function ppoints, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, using the quantile function for the sample, and the function specified as the distribution argument for the theoretical distribution.

f.value defaults to NULL, which has the effect of using ppoints for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for qqnorm, but different from the S-PLUS default of f.value=ppoints.

For large x, this argument can be useful in plotting a smaller set of quantiles, which is usually enough to capture the pattern.

panel The panel function to be used. Unlike in older versions, the default panel function does most of the actual computations and has support for grouping. See panel.qqmath for details.

Details

qqmath produces a Q-Q plot of the given sample and a theoretical distribution. The default behaviour of qqmath is different from the corresponding S-PLUS function, but is similar to qqnorm. See the entry for f.value for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the panel (and prepanel function) and not qqmath itself. In fact, both the arguments distribution and f.value are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for panel.qqmath for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for xyplot, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.
**rfs**

**Residual and Fit Spread Plots**

**Description**

Plots fitted values and residuals (via `qqmath`) on a common scale for any object that has methods for fitted values and residuals.

**Usage**

```r
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
   distribution = qunif,
   panel, prepanel, strip, ...)```

**Examples**

```r
qqmath(~ rnorm(100), distribution = function(p) qt(p, df = 10))
qqmath(~ height | voice.part, aspect = "xy", data = singer,
    prepanel = prepanel.qqmathline,
    panel = function(x, ...) {
        panel.qqmathline(x, ...)
        panel.qqmath(x, ...)
    })
vp.comb <-
    factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
        
        "[", 1),
        levels = c("Bass", "Tenor", "Alto", "Soprano"))
vp.group <-
    factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
        
        
        
        "[", 2))
qqmath(~ height | vp.comb, data = singer,
    groups = vp.group, auto.key = list(space = "right"),
    aspect = "xy",
    prepanel = prepanel.qqmathline,
    panel = function(x, ...) {
        panel.qqmathline(x, ...)
        panel.qqmath(x, ...)
    })
```
shingles

Arguments

model  a fitted model object with methods fitted.values and residuals. Can be the value returned by oneway
layout  default layout is c(2,1)
xlab  defaults to "f.value"
distribution  the distribution function to be used for qqmath
ylab, panel, prepanel, strip
See xyplot

...  other arguments, passed on to qqmath.

Value

An object of class "trellis". The update method can be used to update components of the object and the print method (usually called by default) will plot it on an appropriate plotting device.

rfs(oneway(height ~ voice.part, data = singer, spread = 1), aspect = 1)

Description

Functions to handle shingles

Usage

shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle':
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle':

print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel':
as.character(x, ...)

## S3 method for class 'shingleLevel':
print(x, ...)

## S3 method for class 'shingle':
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle':
x[subset, drop = FALSE]

as.factorOrShingle(x, subset, drop)

Arguments

x
numeric variable or R object, shingle in `plot.shingle` and `x[]`. An object
(list of intervals) of class "shingleLevel" in `print.shingleLevel`

object
shingle object to be summarized

showValues
logical, whether to print the numeric part. If FALSE, only the intervals are
printed

intervals
numeric vector or matrix with 2 columns

subset
logical vector

drop
whether redundant shingle levels are to be dropped

panel, xlab, ylab
standard Trellis arguments (see `xyplot`)

...
other arguments, passed down as appropriate. For example, extra arguments to
equal.count are passed on to `co.intervals`. Graphical parameters can
be passed as arguments to the `plot` method.

Details

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ vari-
ables. It consists of a numeric vector along with some possibly overlapping intervals. These inter-
vals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to
factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to
a shingle. For use in labelling, the `as.character` method can be used to convert levels of a
shingle to character strings.

equal.count converts `x` to a shingle using the equal count algorithm. This is essentially a
wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

shingle creates a shingle using the given intervals. If `intervals` is a vector, these are
used to form 0 length intervals.

as.shingle returns `shingle(x)` if `x` is not a shingle.
is.shingle tests whether \textit{x} is a shingle.

plot.shingle displays the ranges of shingles via rectangles. print.shingle and summary.shingle describe the shingle object.

Value

\texttt{x$intervals} for \texttt{levels.shingle(x)}, \texttt{logical} for \texttt{is.shingle}, an object of class \texttt{"trellis"} for \texttt{plot} (printed by default by \texttt{print.trellis}), and an object of class \texttt{"shingle"} for the others.

---

\texttt{simpleKey} \hspace{1cm} \textit{Function to generate a simple key}

Description

Simple interface to generate a list appropriate for \texttt{draw.key}

Usage

\begin{verbatim}
simpleKey(text, points = TRUE, rectangles = FALSE, lines = FALSE, col, cex, alpha, font, fontface, fontfamily, lineheight, \ldots)
\end{verbatim}
Arguments

text character or expression vector, to be used as labels for levels of the grouping variable
points logical
rectangles logical
lines logical
col, cex, alpha, font, fontface, fontfamily, lineheight
   Used as top-level components of the list produced, to be used for the text labels.
   Defaults to the values in trellis.par.get("add.text")
...
   further arguments added to the list, eventually passed to draw.key

Details

A lattice plot can include a legend (key) if an appropriate list is specified as the key argument to a high level Lattice function such as xyplot. This key can be very flexible, but that flexibility comes at the cost of this list being very complicated even in simple situations. The simpleKey function is a shortcut, which assumes that the key is being drawn in conjunction with the groups argument, and that the default Trellis settings are being used. At most one each of points, rectangles and lines can be drawn.

See also the auto.key argument for high level plots.

Value

A list that would work as the key argument to xyplot etc.

draw.key, xyplot, Lattice

simpleTheme Function to generate a simple theme

Description

Simple interface to generate a list appropriate as a theme, typically used as the par.settings argument in a high level call

Usage

simpleTheme(col, alpha,
   cex, pch, lty, lwd, font, fill, border,
   col.points, col.line,
   alpha.points, alpha.line)
Arguments

col, col.points, col.line

A color specification. \texttt{col} is used for components \texttt{plot.symbol, plot.line, plot.polygon, superpose.symbol, superpose.line,} and \texttt{superpose.polygon}. \texttt{col.points} overrides \texttt{col}, and is used only for \texttt{plot.symbol and superpose.symbol}. Similarly, \texttt{col.lines} overrides \texttt{col} for \texttt{plot.line and superpose.line}. The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

alpha, alpha.points, alpha.line

A numeric alpha transparency specification. The same rules as \texttt{col}, etc., apply.

cex, pch, font

Parameters for points. Applicable for components \texttt{plot.symbol} (for which only the first component is used) and \texttt{superpose.symbol} (for which the arguments can be vectors).

lty, lwd

Parameters for lines. Applicable for components \texttt{plot.line} (for which only the first component is used) and \texttt{superpose.line} (for which the arguments can be vectors).

fill

fill color, applicable for components \texttt{plot.symbol, plot.polygon, superpose.symbol, and superpose.polygon}.

border

border color, applicable for components \texttt{plot.polygon} and \texttt{superpose.polygon}.

Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see \texttt{trellis.device} for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the \texttt{auto.key} argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the \texttt{par.settings} argument, which is usually tedious to construct as it is a nested list. The \texttt{simpleKey} function can be used in such situations as a wrapper that generates a suitable list given parameters in simple \texttt{name=value} form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

Value

A list that would work as the \texttt{theme} argument to \texttt{trellis.device} and \texttt{trellis.par.set}, or as the \texttt{par.settings} argument to any high level lattice function such as \texttt{xyplot}.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org), based on a suggestion from John Maindonald.

str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
          auto.key = list(space = "right"),
          par.settings = simpleTheme(pch = 16),
          xlab = "Barley Yield (bushels/acre) ",
          aspect=0.5, layout = c(1,6))
```

---

singer

Heights of New York Choral Society singers

Description

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

Usage

singer

Format

A data frame with 235 observations on the following 2 variables.

- **height**  Height in inches of the singers.
- **voice.part**  (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

## S3 method for class 'matrix':
splom(x, data = NULL, ...)
## S3 method for class 'matrix':
parallel(x, data = NULL, ...)
## S3 method for class 'data.frame':
parallel(x, data = NULL, ...)

Arguments

x

The object on which method dispatch is carried out.

For the "formula" method, a formula describing the structure of the plot, which should be of the form ~ x | g1 * g2 * ..., where x is a data frame or matrix. Each of g1, g2, ... must be either factors or shingles. The conditioning variables g1, g2, ... may be omitted.
For the \texttt{data.frame} methods, a data frame.

\textbf{data} \hspace{1cm} \texttt{data} For the \texttt{formula} methods, an optional data frame in which variables in the formula (as well as \texttt{groups} and \texttt{subset}, if any) are to be evaluated.

\textbf{aspect} \hspace{1cm} \texttt{aspect} aspect ratio of each panel (and subpanel), square by default for \texttt{splom}.

\textbf{between} \hspace{1cm} \texttt{between} to avoid confusion between panels and subpanels, the default is to show the panels of a splom plot with space between them.

\textbf{panel} \hspace{1cm} \texttt{panel} Usual interpretation for \texttt{parallel}, namely the function that creates the display within each panel.

For \texttt{splom}, the terminology is slightly complicated. The role played by the \texttt{panel} function in most other high-level functions is played here by the \texttt{superpanel} function, which is responsible for the display for each conditional data subset. \texttt{panel} is simply an argument to the default \texttt{superpanel} function \texttt{panel.pairs}, and is passed on to it unchanged. It is used there to create each pairwise display. See \texttt{panel.pairs} for more useful options.

\textbf{superpanel} \hspace{1cm} \texttt{superpanel} function that sets up the splom display, by default as a scatterplot matrix.

\textbf{pscales} \hspace{1cm} \texttt{pscales} a numeric value or a list, meant to be a less functional substitute for the \texttt{scales} argument in \texttt{xyplot} etc. This argument is passed to the \texttt{superpanel} function, and is handled by the default \texttt{superpanel} function \texttt{panel.pairs}. The help page for the latter documents this argument in more detail.

\textbf{varnames} \hspace{1cm} \texttt{varnames} character vector giving the names of the \texttt{p} variables in \texttt{x}. By default, the column names of \texttt{x}.

\textbf{auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset} \hspace{1cm} \texttt{auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.options, default.scales, subset} See \texttt{xyplot} ...

Further arguments. See corresponding entry in \texttt{xyplot} for non-trivial details.

\textbf{Details} \hspace{1cm} \texttt{Details} \texttt{splom} produces Scatter Plot Matrices. The role usually played by \texttt{panel} is taken over by \texttt{superpanel}, which determines how the columns of \texttt{x} are to be arranged for pairwise plots. The only available option currently is \texttt{panel.pairs}.

Many of the finer customizations usually done via arguments to high level function like \texttt{xyplot} are instead done by \texttt{panel.pairs} for \texttt{splom}. These include control of axis limits, tick locations and prepanel calculations. If you are trying to fine-tune your \texttt{splom} plot, definitely look at the \texttt{panel.pairs} help page. The \texttt{scales} argument is usually not very useful in \texttt{splom}, and trying to change it may have undesired effects.

\texttt{parallel} draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for \texttt{xyplot}, which should be consulted to learn more detailed usage.

\textbf{Value} \hspace{1cm} \texttt{Value} An object of class "\texttt{trellis}". The \texttt{update} method can be used to update components of the object and the \texttt{print} method (usually called by default) will plot it on an appropriate plotting device.
strip.default

Default Trellis Strip Function

Description

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

Usage

```r
strip.default(which.given, which.panel, var.name, factor.levels, shingle.intervals, strip.names = c(FALSE, TRUE), strip.levels = c(TRUE, FALSE), sep = " ",
```
style = 1,
horizontal = TRUE,
bg = trellis.par.get("strip.background")$col[which.given],
fg = trellis.par.get("strip.shingle")$col[which.given],
par.strip.text = trellis.par.get("add.text")
strip.custom(...)

Arguments

which.given integer index specifying which of the conditioning variables this strip corresponds to.

which.panel vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of which.packet, which is a more accurate name.

var.name vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of strip.names and style (see below). By default, the names are shown for shingles, but not for factors.

factor.levels vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with which.given. Whether these levels are shown on the strip depends on the values of strip.levels and style (see below). factor.levels may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in par.strip.text (see xyplot)

shingle.intervals if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by printing levels(shingle)). Otherwise, it should be NULL.

strip.names a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when style is not one of 1 and 3.

strip.levels a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.

sep character or expression, serving as a separator if the name and level are both to be shown.

style integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when shingle.intervals is non-null.
The best way to find out what effect the value of style has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the

...
background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.

Note that unlike S-PLUS, the default value of style is 1. strip.names and strip.levels have no effect if style is not 1 or 3.

horizontal logical, specifying whether the labels etc should be horizontal. horizontal=FALSE is useful for strips on the left of panels using strip.left=TRUE

par.strip.text list with parameters controlling the text on each strip, with components col, cex, font, etc.

bg strip background color.

fg strip foreground color.

... arguments to be passed on to strip.default, overriding whatever value it would have normally assumed

Details
default strip function for trellis functions. Useful mostly because of the style argument — non-default styles are often more informative, especially when the names of the levels of the factor x are small. Traditional use is as strip = function(...) strip.default(style=2,...), though this can be simplified by the use of strip.custom.

Value

strip.default is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. strip.custom returns a function that is similar to strip.default, but with different defaults for the arguments specified in the call.

xyplot,Lattice

Examples

## Traditional use

xyplot(Petal.Length ~ Petal.Width | Species, iris,
    strip = function(..., style) strip.default(..., style = 4))
## equivalent call using strip.custom

```r
xyplot(Petal.Length ~ Petal.Width | Species, iris,
      strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
      strip = FALSE,
      strip.left = strip.custom(style = 4, horizontal = FALSE))
```

---

**tmd**

**Tukey Mean-Difference Plot**

### Description

`tmd` creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The prepanel and panel functions are used as appropriate. The `formula` method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

### Usage

```r
tmd(object, ...)
```

## S3 method for class 'trellis':

```r
tmd(object,
    xlab = "mean",
    ylab = "difference",
    panel,
    prepanel,
    ...)
```

```r
prepanel.tmd.qqmath(x,
    f.value = NULL,
    distribution = qnorm,
    qtype = 7,
    groups = NULL,
    subscripts, ...)
```

```r
panel.tmd.qqmath(x,
    f.value = NULL,
    distribution = qnorm,
    qtype = 7,
    groups = NULL,
    subscripts, ...)
```

```r
panel.tmd.default(x, y, groups = NULL, ...)
```

```r
prepanel.tmd.default(x, y, ...)
```
Arguments

- **object**: An object of class "trellis" returned by `xyplot`, `qq` or `qqmath`.
- **xlab**: x label
- **ylab**: y label
- **panel**: panel function to be used. See details below.
- **prepanel**: prepanel function. See details below.
- **f.value, distribution, qtype**: see `panel.qqmath`.
- **groups, subscripts**: see `xyplot`.
- **x, y**: data as passed to panel functions in original call.
- **...**: other arguments

Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by \( x=(x+y)/2 \) and \( y=y-x \), which are then plotted. The default panel function(s) add a reference line at \( y=0 \) as well.

`tmd` acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. `tmd` uses these panel arguments to set up its own scales (using its `prepanel` argument) and display (using `panel`). It is thus important to provide suitable `prepanel` and `panel` functions to `tmd` depending on the original call.

Such functions currently exist for `xyplot`, `qq` (the ones with `default` in their name) and `qqmath`, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the code `prepanel` and `panel` arguments default to suitable choices.

`tmd` uses the `update` method for "trellis" objects, which processes all extra arguments supplied to `tmd`.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

trellis.device

Initializing Trellis Displays

Description

Initialization of a display device with appropriate graphical parameters.

Usage

trellis.device(device = getOption("device"),
               color = !(dev.name == "postscript"),
               theme = lattice.getOption("default.theme"),
               new = TRUE,
               retain = FALSE,
               ...
)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()

Arguments

device function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see Devices), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.
color logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using theme or subsequent calls to trellis.par.set (and by arguments supplied directly in high level calls for some settings).
theme list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying lattice.options(default.theme = "col.whitebg"). For back-compatibility, this is initially (when lattice is loaded) set to options(lattice.theme). If theme is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use .Device inside the function to ascertain what device has been opened.
new logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.

retain logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).

name name of the device for which the setting is required, as returned by .Device

... additional parameters to be passed to the device function, most commonly file for non-screen devices, as well as height, width, etc. See the help file for individual devices for admissible arguments.

Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to \code{par} for standard \proglang{R} graphics and, together with \code{lattice.options}, mostly supplants it (\code{par} settings are mostly ignored by Lattice). Unlike \code{par}, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). \code{standard.theme} and \code{col.whitebg} produce predefined settings (a.k.a. themes), while \code{trellis.device} provides a high level interface to control which “theme” will be in effect when a new device is opened. \code{trellis.device} is called automatically when a "trellis" object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call \code{trellis.device} explicitly.

The \code{standard.theme} function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to \proglang{R} 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which \proglang{R} is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from \proglang{R} 2.3.0 onwards. The old behaviour can be reinstated by setting \code{standard.theme} as the default \code{theme} argument, e.g. by putting \code{options(lattice.theme = "standard.theme")} in a startup script (see the entry for \code{theme} above for details).

Value

\code{standard.theme} returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in \code{trellis.device}, and can also be used as the \code{theme} argument to \code{trellis.par.set}, or even as \code{theme} in \code{trellis.device} to use the defaults for another device. \code{canonical.theme} is an alias for \code{standard.theme}.

\code{col.whitebg} returns a similar (but smaller) list that is suitable as the \code{theme} argument to \code{trellis.device} and \code{trellis.par.set}. It contains settings values which provide colors suitable for plotting on a white background. Note that the name \code{col.whitebg} is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

Note

Earlier versions of \code{trellis.device} had a \code{bg} argument to set the background color, but this is no longer supported. If supplied, the \code{bg} argument will be passed on to the device function; however,
this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the theme argument instead.

trellis.par.get and trellis.par.set can be used to query and modify the settings after a device has been initialized. The par.settings argument to high level functions, described in xyplot, can be used to attach transient settings to a "trellis" object.

trellis.object A Trellis Plot Object

Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by its print method.

Details

A trellis object, as returned by high level lattice functions like xyplot, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: as.table, layout, page, panel, prepanel, main, sub, par.strip.text, strip, skip, xlab, ylab, par.settings, lattice.options and plot.args. Some other typical components are:

formula the Trellis formula used in the call

index.cond list with index for each of the conditioning variables

perm.cond permutation of the order of the conditioning variables

aspect.fill logical, whether aspect is "fill"

aspect.ratio numeric, aspect ratio to be used if aspect.fill is FALSE

call call that generated the object.

condlevels list with levels of the conditioning variables

legend list describing the legend(s) to be drawn

panel.args a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.

panel.args.common a list containing the arguments common to all the panel functions in name=value form
**x.scales** list describing x-scale, can consist of several other lists, paralleling panel.args, if x-relation is not "same"

**y.scales** list describing y-scale, similar to x.scales

**x.between** numeric vector of interpanel x-space

**y.between** numeric vector of interpanel y-space

**x.limits** numeric vector of length 2 or list, giving x-axis limits

**y.limits** similar to x.limits

**packet.sizes** array recording the number of observations in each packet

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

**See Also**

Lattice, xyplot, print.trellis

**Description**

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

**Usage**

```r
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)
```

**Arguments**

- **name** character giving the name of a component. If unspecified, names(trellis.par.get()) returns a list containing all the current settings (this can be used to get the valid values for name)

- **value** a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in value will remain unchanged.

- **theme** a list describing how to change the settings, similar to what is returned by trellis.par.get(). This is purely for convenience, allowing multiple calls to trellis.par.set to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.

  As in trellis.device, theme can also be a function that produces such a list when called. The function name can be supplied as a quoted string.
Multiple settings can be specified in `name = value` form. Equivalent to calling with `theme = list(...)`

- `warn` logical, indicating whether a warning should be issued when `trellis.par.get` is called when no graphics device is open
- `strict` logical, indicating whether the `value` should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from `value` but not currently NULL are retained. By specifying `strict = TRUE`, the assignment will be exact.
- `x` optional list of components that change the settings (any valid value of `theme`). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (color `postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a postscript device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

- `trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

- `trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```r
add.line <- trellis.par.get("add.line")
add.line$col <- "red"
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```r
trellis.par.set(list(add.line = list(col = "red")))
```

and
trellis.par.set(add.line = list(col = "red"))

The actual list of the components in trellis.settings has not been finalized, so I’m not attempting to list them here. The current value can be obtained by print(trellis.par.get()). Most names should be self-explanatory.

show.settings provides a graphical display summarizing some of the values in the current settings.

Value

trellis.par.get returns a list giving parameters for that component. If name is missing, it returns the full list.

Note

In some ways, trellis.par.get and trellis.par.set together are a replacement for the par function used in traditional R graphics. In particular, changing par settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system does have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the grid.pars component (see gpar for a list of valid parameter names).

One of the uses of par is to set par(ask = TRUE) making R wait for user input before starting a new graphics page. For Grid graphics, this is done using grid.prompt. Lattice has no separate interface for this, and the user must call grid.prompt directly. If the grid package is not attached (lattice itself only loads the grid namespace), this may be done using grid::grid.prompt(TRUE).

Examples

show.settings()

update.trellis Retrieve and Update Trellis Object

Description

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).
Usage

```r
## S3 method for class 'trellis':
update(object,
       panel,
       aspect,
       as.table,
       between,
       key,
       auto.key,
       legend,
       layout,
       main,
       page,
       par.strip.text,
       prepanel,
       scales,
       skip,
       strip,
       strip.left,
       sub,
       xlab,
       xlim,
       ylab,
       ylim,
       par.settings,
       index.cond,
       perm.cond,
       ...)
```

```r
## S3 method for class 'trellis':
t(x)
```

```r
## S3 method for class 'trellis':
x[i, j, ..., drop = FALSE]
```

```r
trellis.last.object(warn = TRUE, ...)
```

Arguments

- `object, x` The object to be updated, of class "trellis".
- `i, j` indices to be used. Names are not currently allowed.
- `drop` logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.
- `warn` logical, whether to warn when no plot is saved.
- `panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip.text, ...` arguments that will be used to update `object`. See details below.
Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would need to change the data within each panel is a no-no (this includes the formula, data, groups, subscripts and subset). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for `xyplot`. Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The "[]" method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The print method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. Note that at most one object can be saved at a time. If `trellis.last.object` is called with arguments, these are used to update the retrieved object before returning it.

Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns NULL if no saved object is available.

trellis.object, Lattice, xyplot

Examples

```r
spots <- by(sunspots, gl(235, 12, lab = 1749:1983), mean)
old.options <- lattice.options(save.object = TRUE)
xyplot(spots ~ 1749:1983, xlab = "", type = "l",
scales = list(x = list(alternating = 2)),
main = "Average Yearly Sunspots")
update(trellis.last.object(), aspect = "xy")
## Not run:
trellis.last.object(xlab = "Year")
## End(Not run)
lattice.options(old.options)
```
Description

These are (related to) the default panel functions for `cloud` and `wireframe`.

Usage

```r
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)
```

Arguments

- `x`  
  - `x` can be a numeric matrix with 3 rows for `ltransform3dto3d`
- `screen`  
  - list, as described in `panel.cloud`
- `R.mat`  
  - 4x4 transformation matrix in homogeneous coordinates
- `dist`  
  - controls transformation to account for perspective viewing

Details

`ltransform3dMatrix` and `ltransform3dto3d` are utility functions to help in computation of projections. These functions are used inside the panel functions for `cloud` and `wireframe`. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the `screen` argument in `cloud` and `wireframe` and a `R.mat`, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying `R.mat` followed by the rotations in `screen`. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

`cloud`, `panel.cloud`
Common Bivariate Trellis Plots

Description
These are the most commonly used high level Trellis functions to plot pairs of variables. By far the most common is `xyplot`, designed mainly for two continuous variates (though factors can be supplied as well, in which case they will simply be coerced to numeric), which produces Conditional Scatter plots. The others are useful when one of the variates is a factor or a shingle. Most of these arguments are also applicable to other high level functions in the lattice package, but are only documented here.

Usage

```r
xyplot(x, data, ...)  
dotplot(x, data, ...)  
barchart(x, data, ...)  
stripplot(x, data, ...)  
bwplot(x, data, ...)  

## S3 method for class 'formula':  
xyplot(x,  
data,  
allow.multiple = is.null(groups) || outer,  
outer = !is.null(groups),  
auto.key = FALSE,  
aspect = "fill",  
panel = lattice.getOption("panel.xyplot"),  
prepanel = NULL,  
scales = list(),  
strip = TRUE,  
groups = NULL,  
xlab,  
xlim,  
ylab,  
ylim,  
drop.unused.levels = lattice.getOption("drop.unused.levels"),  
...,  
lattice.options = NULL,  
default.scales,  
subscripts = !is.null(groups),  
subset = TRUE)

## S3 method for class 'formula':  
dotplot(x,  
data,  
panel = lattice.getOption("panel.dotplot"),  

```
Arguments

x

The object on which method dispatch is carried out.

For the "formula" methods, a formula describing the form of conditioning plot. The formula is generally of the form y ~ x | g1 * g2 * ..., indicating that plots of y (on the y axis) versus x (on the x axis) should be produced conditional on the variables g1, g2, ... However, the conditioning variables g1, g2, ... may be omitted. The formula can also be supplied as y ~
xyplot

x | g1 + g2 + ....

For all of these functions, with the exception of xyplot, a formula of the form \( ~ x | g1 + g2 + ... \) is also allowed. In that case, \( y \) defaults to \( \text{names}(x) \) if \( x \) is named, and a factor with a single level otherwise.

Other usage of the form dotplot \((x)\) is handled by method dispatch as appropriate. The numeric method is equivalent to a call with no left hand side and no conditioning variables in the formula. For barchart and dotplot, non-trivial methods exist for tables and arrays, documented under barchart.table. The conditioning variables \( g1, g2, \ldots \) must be either factors or shingles. Shingles are a way of processing numeric variables for use in conditioning. See documentation of shingle for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots.

Numeric conditioning variables are converted to shingles by the function shingle (however, using equal.count might be more appropriate in many cases) and character vectors are coerced to factors.

The formula can involve expressions, e.g. \( \text{sqrt}(), \text{log}() \).

A special case is when the left and/or right sides of the formula (before the conditioning variables) contain a ‘+’ sign, e.g., \( y1 + y2 ~ x | a + b \). This formula would be taken to mean that the user wants to plot both \( y1 ~ x | a + b \) and \( y2 ~ x | a + b \), but with the \( y1 ~ x \) and \( y2 ~ x \) superposed in each panel (this is slightly more complicated in barchart). The two parts would be distinguished by different graphical parameters. This is essentially what the groups argument would produce, if \( y1 \) and \( y2 \) were concatenated to produce a longer vector, with the groups argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the reshape function. This feature cannot be used in conjunction with the groups argument.

To interpret \( y1 + y2 \) as a sum, one can either set allow.multiple=FALSE or use I\((y1+y2)\).

A variation on this feature is when the outer argument is set to TRUE as well as allow.multiple. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

The \( x \) and \( y \) variables should both be numeric in xyplot, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of \( x \) and \( y \) should be numeric, and the other a factor or shingle. Which of these will happen is determined by the horizontal argument — if horizontal=TRUE, then \( y \) will be coerced to be a factor or shingle, otherwise \( x \). The default value of horizontal is FALSE if \( x \) is a factor or shingle, TRUE otherwise. (The functionality provided by horizontal=FALSE is not S-compatible.)

Note that this argument used to be called formula in earlier versions (when the high level functions were not generic and the formula method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but rather be the first (unnamed) argument.

data

For the formula method, a data frame containing values (or more precisely,
anything that is a valid \texttt{envir} argument in \texttt{eval}, e.g. a list or an environment) for any variables in the formula, as well as \texttt{groups} and \texttt{subset} if applicable. If not found in \texttt{data}, or if \texttt{data} is unspecified, the variables are looked for in the environment of the formula. For other methods (where \texttt{x} is not a formula), \texttt{data} is usually ignored, often with a warning.

\texttt{allow.multiple, outer}
logical flags to control what happens with formulas like \texttt{y1 + y2 ~ x}. See the entry for \texttt{x} for details. \texttt{allow.multiple} defaults to \texttt{TRUE} whenever it makes sense, and \texttt{outer} defaults to \texttt{FALSE} except when \texttt{groups} is explicitly specified or grouping doesn't make sense for the default panel function

\texttt{box.ratio}
applicable to \texttt{bwplot, barchart} and \texttt{stripplot}, specifies the ratio of the width of the rectangles to the inter rectangle space.

\texttt{horizontal}
logical, applicable to \texttt{bwplot, dotplot, barchart} and \texttt{stripplot}. Determines which of \texttt{x} and \texttt{y} is to be a factor or shingle (\texttt{y} if \texttt{TRUE}, \texttt{x} otherwise). Defaults to \texttt{FALSE} if \texttt{x} is a factor or shingle, \texttt{TRUE} otherwise. This argument is used to process the arguments to these high level functions, but more importantly, it is passed as an argument to the panel function, which is supposed to use it as appropriate.

A potentially useful component of \texttt{scales} in this case might be \texttt{abbreviate = TRUE}, in which case long labels which would usually overlap will be abbreviated. \texttt{scales} could also contain a \texttt{minlength} argument in this case, which would be passed to the \texttt{abbreviate} function.

\texttt{panel}
Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see details), the corresponding \texttt{x} and \texttt{y} variables (or other variables, as appropriate, in the case of other high level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the \texttt{panel} argument. Each high level function has its own default panel function, which could depend on whether the \texttt{groups} argument was supplied.

The panel function can be a function object or a character string giving the name of a predefined function.

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named \texttt{x} and \texttt{y}, which would be provided by the conditioning process. It can also have other arguments. It might be useful to know in this context that all arguments passed to a high level Trellis function (such as \texttt{xyplot}) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a \ldots argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the \texttt{x} and \texttt{y} arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new
custom panel functions, there are several predefined panel functions which can help: for example, \texttt{panel.grid}, \texttt{panel.loess}, etc. There are also some grid-compatible replacements of commonly used base R graphics functions useful for this purpose. For example, \texttt{lines} can be replaced by \texttt{lilines} (or equivalently, \texttt{panel.lines}). Note that base R graphics functions like \texttt{lines} will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the \texttt{groups} argument is not null. In that case, the panel function should also accept arguments named \texttt{groups} and \texttt{subscripts} (see below for details). A useful panel function predefined for use in such cases is \texttt{panel.superpose}, which can be combined with different \texttt{panel.groups} functions determining what is plotted for each group. See the examples section for an interaction plot constructed in this way. Several other panel functions can also handle the \texttt{groups} argument, including the default ones for \texttt{barchart}, \texttt{dotplot} and \texttt{stripplot}.

Even when \texttt{groups} is not present, the panel function can have \texttt{subscripts} as a formal argument. In either case, the \texttt{subscripts} argument passed to the panel function are the indices of the \texttt{x} and \texttt{y} data for that panel in the original \texttt{data}, BEFORE taking into account the effect of the \texttt{subset} argument. Note that \texttt{groups} remains unaffected by any subsetting operations, so \texttt{groups[subscripts]} gives the values of \texttt{groups} that correspond to the data in that panel. The value of \texttt{subscripts} becomes slightly more complicated when \texttt{allow.multiple} is in effect. Details can be found in the source code of the function \texttt{latticeParseFormula}.

One can also use functions called \texttt{panel.number} and \texttt{packet.number}, representing panel order and packet order respectively, inside the panel function (as well as the strip function or while interacting with a lattice display using \texttt{trellis.focus} etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using \texttt{perm.cond} and \texttt{index.cond} respectively), in which case \texttt{packet.number} gives the index corresponding to the ‘natural’ ordering of that combination of levels of the conditioning variables.

\texttt{panel.xyplot} has an argument called \texttt{type} which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to \texttt{xyplot} directly). In the event that a \texttt{groups} variable is used, \texttt{panel.xyplot} calls \texttt{panel.superpose}, arguments of which can also be passed directly to \texttt{xyplot}. Panel functions for \texttt{bwplot} and friends should have an argument called \texttt{horizontal} to account for the cases when \texttt{x} is the factor or shingle.

\texttt{aspect} controls physical aspect ratio of the panels (same for all the panels). It can be specified as a ratio (vertical size/horizontal size) or as a character string. Legitimate values are "fill" (the default) which tries to make the panels as big as possible to fill the available space; "xy", which \texttt{tries} to compute the aspect based on the 45 degree banking rule (see \textit{Visualizing Data} by William
S. Cleveland for details); and "iso" for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default prepanel function are used. Currently, only the default prepanel function for `xyplot` can be expected to produce sensible banking calculations. See `banking` for details on the implementation of banking.

groups

A variable or expression to be evaluated in the data frame specified by `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. Not all pre-defined panel functions know how to, but for high level functions where grouping is appropriate, the default panel functions are chosen so that they do.

It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and `simpleKey` for how to draw a key.

auto.key

A logical (indicating whether a key is to be drawn automatically when a grouping variable is present in the plot), or a list of parameters that would be valid arguments to `simpleKey` (in effect, most valid components of `key` can be specified in this manner). If `auto.key` is not `FALSE`, `groups` is non-null and there is no `key` or `legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first argument. (Note: this may not work in all high level functions, but it does work for the ones where grouping makes sense with the default panel function)

simpleKey uses the trellis settings to determine the graphical parameters in the key, so this will be meaningful only if the settings are used in the plot as well.

One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is reprinted with different settings, the parameter settings for the original device will be used. However, with `auto.key`, the key is actually created at printing time, so the key settings will match the device settings.

prepanel

A function that takes the same arguments as the `panel` function and returns a list, possibly containing components named `xlim`, `ylim`, `dx` and `dy` (and less frequently, `xat` and `yat`).

The `xlim` and `ylim` components are similar to the high level `xlim` and `ylim` arguments (i.e., they are usually a numeric vector of length 2 defining a range of values, or a character vector representing levels of a factor). If the `xlim` and `ylim` arguments are not explicitly specified (possibly as components in `scales`), then the actual limits of the panels are guaranteed to include the limits returned by the prepanel function. This happens globally if the `relation` component of `scales` is "same", and on a panel by panel basis otherwise. See `xlim` to see what forms of the components `xlim` and `ylim` are allowed.

The `dx` and `dy` components are used for banking computations in case `aspect` is specified as "xy". See documentation for the function `banking` for details.
regarding how this is done.

The return value of the prepanel function need not have all the components named above; in case some are missing, they are replaced by the usual component-wise defaults.

If xlim or ylim is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first \( n \) integers, where \( n \) is the length of xlim or ylim, as the case may be. The elements of the character vector are used as the default labels for these \( n \) integers. Thus, to make this information consistent between panels, the xlim or ylim values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component xat or yat may be returned by the prepanel function, which should be a subset of 1:n, indicating which of the \( n \) values (levels) are actually represented in the panel. This is useful when calculating the limits with relation="free" or relation="sliced" in scales.

The prepanel function is responsible for providing a meaningful return value when the x, y (etc.) variables are zero-length vectors. When nothing is appropriate, values of NA should be returned for the xlim and ylim components.

strip

logical flag or function. If FALSE, strips are not drawn. Otherwise, strips are drawn using the strip function, which defaults to strip.default. See documentation of strip.default to see the arguments that are available to the strip function. This description also applies to the strip.left argument (see ... below), which can be used to draw strips on the left of each panel, which can be useful for wide short panels, e.g. in time series plots.

xlab

character string or expression (or a "grob") giving label for the x-axis. Defaults to the expression for x in formula. Can be specified as NULL to omit the label altogether. Finer control is possible, as described in the entry for main, with the additional feature that if the label component is omitted from the list, it is replaced by the default xlab.

ylab

character string or expression (or "grob") giving label for the y-axis. Defaults to the expression for y in formula. Fine control is possible, see entries for main and xlab.

scales

list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in name=value form, and may also contain two other lists called x and y of the same form (described below). Components of x and y affect the respective axes only, while those in scales affect both. When parameters are specified in both lists, the values in x or y are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., bwplot has alternating=FALSE for the y-axis only); these can be overridden only by an entry in the corresponding component of scales.

The possible components are:

relation character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For relation="same", the same limits, usually large enough to encompass all the data, are used for all the panels. For relation="free",
limits for each panel is determined by just the points in that panel. Behavior for relation="sliced" is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the prepanel function, which can be overridden by xlim, ylim or scales$limits. If relation is not "same", the value of xlim etc is normally ignored, except when it is a list, in which case it is treated as if its components were the limit values obtained from the prepanel calculations for each panel.

tick.number Suggested number of ticks (ignored for a factor, shingle or character vector, in which case there is no natural rule for leaving out some of the labels. But see xlim).

draw logical, defaults to TRUE, whether to draw the axis at all.

alternating logical specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, alternating can be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers
  • 0: do not draw tick labels
  • 1: bottom/left
  • 2: top/right
  • 3: both.

alternating applies only when relation="same". The default is TRUE, or equivalently, c(1, 2)

limits same as xlim and ylim.

at location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.

labels Labels (strings or expressions) to go along with at. Can be a list like at as well.

cex numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top separately.

font, fontface, fontfamily specifies font for axis labels.

tck numeric to control length of tick marks. Can be a vector of length 2, to control left/bottom and right/top separately.

col color of ticks and labels.

rot Angle by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top separately.

abbreviate logical, whether to abbreviate the labels using abbreviate. Can be useful for long labels (e.g., in factors), especially on the x-axis.

minlength argument passed to abbreviate if abbreviate=TRUE.

log Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is a transformation of the data,
not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., scales=list(x=list(log = 2)) is equivalent to y ~ log2(x).

**format** the format to use for POSIXct variables. See `strptime` for description of valid values.

**axis** character, "r" or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of `scales` is accomplished by `pscales` in `splom`.

**subscripts** logical specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to `FALSE`, unless `groups` is specified, or if the panel function accepts an argument named subscripts. (One should be careful when defining the panel function on-the-fly.)

**subset** logical or integer indexing vector (can be specified in terms of variables in `data`). Only these rows of `data` will be used for the plot. If `subscripts` is `TRUE`, the subscripts will provide indices to the rows of data before the subsetting is done. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the `drop.unused.levels` argument.

**xlim** Normally a numeric vector of length 2 (possibly a DateTime object) giving minimum and maximum for the x-axis, or, a character vector, expected to denote the levels of `x`. The latter form is interpreted as a range containing `c(1, length(xlim))`, with the character vector determining labels at tick positions `1:length(xlim)`.

xlim could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when `scales$x$relation` is "free" or "sliced", in which case these are treated as if they were the corresponding limit components returned by prepanel calculations.

**ylim** similar to `xlim`, applied to the y-axis.

**drop.unused.levels** logical indicating whether the unused levels of factors will be dropped, usually relevant with a subsetting operation is performed or an interaction is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components cond and data, both logical, indicating desired behavior for conditioning variables and data variables respectively. The default is given by `lattice.getOption("drop.unused.levels")`, which is initially set to `TRUE` for both components. Note that this argument does not control dropping of levels of the `groups` argument.

**default.scales** list giving the default values of `scales` for a particular high level function. This should not be of any interest to the normal user, but may be helpful when defining other functions that act as a wrapper to one of the high level lattice functions.

**lattice.options** a list that could be supplied to `lattice.options`. These options are temporarily in effect for the duration of the call, after which the settings revert back
to whatever they were before. The settings are also retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the \texttt{par.settings} argument described below for a similar treatment of graphical settings.

... further arguments, usually not directly processed by the high level functions documented here, but rather passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high level Trellis functions in a similar manner, and those that are meant for the specific panel function used, which may differ across high level functions.

The first group of arguments are processed by a common, unexported function called \texttt{trellis.skeleton}. These arguments affect all high level functions, but are only documented here, except to override the behaviour described here. All other arguments specified in a high level call, specifically those neither described here nor in the help page of the relevant high level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high level function is named as "panel." followed by the name of the high level function; for example, the default panel function for \texttt{bwplot} is \texttt{panel.bwplot}. In practical terms, this means that in addition to the help page of the high level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high level call.

The effect of the first group of common arguments are as follows:

\textbf{as.table:} logical that controls the order in which panels should be plotted: if \texttt{FALSE} (the default), panels are drawn left to right, bottom to top (as in a graph); if \texttt{TRUE}, left to right, top to bottom.

\textbf{between:} a list with components \texttt{x} and \texttt{y} (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). \texttt{x} and \texttt{y} are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. (In other words, it is not possible to use different \texttt{between} values for different pages).

\textbf{key:} A list of arguments that define a legend to be drawn on the plot. This list is used as an argument to the \texttt{draw.key} function, which produces a grid object eventually plotted by the print method for "trellis" objects.

There is also a less flexible but usually sufficient shortcut function \texttt{simpleKey} that can generate such a list, as well as the argument \texttt{auto.key} that can be convenient in the most common situation where legends are used, namely when there is a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by \texttt{key}, use the \texttt{legend} argument.

The position of the key can be controlled in either of two possible ways. If a component called \texttt{space} is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of \texttt{space}, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components \texttt{x}, \texttt{y} and \texttt{corner}. \texttt{x} and \texttt{y} determine the location of the corner of the key.
given by \texttt{corner}, which is usually one of \texttt{c(0,0)}, \texttt{c(1,0)}, \texttt{c(1,1)} and \texttt{c(0,1)}, which denote the corners of the unit square. Fractional values are also allowed, in which case \texttt{x} and \texttt{y} determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

\texttt{x} and \texttt{y} should be numbers between 0 and 1, giving coordinates with respect to the "display area". Depending on the value of \texttt{lattice.getOption("legend.bbox")}, this can be either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The \texttt{key} list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for \texttt{rep} below for details on this). The "text" component has to have a character or expression vector as its first component, and the length of this vector determines the number of rows.

The graphical components that can be included in \texttt{key} (and also in the components named "text", "lines", "points" and "rectangles" as appropriate) are:

- \texttt{cex=1}
- \texttt{col="black"}
- \texttt{alpha=1}
- \texttt{lty=1}
- \texttt{lwd=1}
- \texttt{font=1}
- \texttt{fontface}
- \texttt{fontfamily}
- \texttt{pch=8}
- \texttt{adj=0}
- \texttt{type="l"}
- \texttt{size=5}
- \texttt{angle=0}
- \texttt{density=-1}

\texttt{angle} and \texttt{density} are currently unimplemented. \texttt{size} determines the width of columns of rectangles and lines in character widths. \texttt{type} is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together.

Other possible components of \texttt{key} are:

- \texttt{reverse.rows} logical, defaulting to \texttt{FALSE}. If \texttt{TRUE}, all components are reversed \texttt{after} being replicated (the details of which may depend
on the value of rep). This is useful in certain situations, e.g. with
a grouped barchart with stack = FALSE with the categorical
variable on the vertical axis, where the bars in the plot will usually be
ordered from bottom to top, but the corresponding legend will have
the levels from top to bottom (unless, of course, reverse.rows =
TRUE). Note that in this case, unless all columns have the same number
or rows, they will no longer be aligned.

between numeric vector giving the amount of space (character widths)
surrounding each column (split equally on both sides)

title string or expression giving a title for the key

rep logical, defaults to TRUE. By default, it's assumed that all columns
in the key (except the "text"s) will have the same number of rows,
and all components are replicated to be as long as the longest. This can
be suppressed by specifying rep=FALSE, in which case the length of
each column will be determined by components of that column alone.

cex.title cex for the title

lines.title how many lines the title should occupy (in multiples of
itself). Defaults to 2.

padding.text how much space (padding) should be used above and
below each row containing text, in multiples of the default, which is
currently 0.2 * "lines". This padding is in addition to the normal
height of any row that contains text, which is the minimum amount
necessary to contain all the text entries.

background background color, defaults to default background

alpha.background An alpha transparency value between 0 and 1

border either a color for the border, or a logical. In the latter case, the
border color is black if border is TRUE, and no border is drawn if it
is FALSE (the default)

transparent=FALSE logical, whether key area should have a transpar-
ent background

columns the number of columns column-blocks the key is to be divided
into, which are drawn side by side.

between.columns Space between column blocks, in addition to between.

divide Number of point symbols to divide each line when type is "b"
or "o" in lines.

legend: the legend argument can be useful if one wants to place more than
one key. It also allows one to use arbitrary "grob"s (grid objects) as
legends.

If used, legend must be a list, with an arbitrary number of components.
Each component must be named one of "left", "right", "top", "bottom"
or "inside". The name "inside" can be repeated, but not the others.
This name will be used to determine the location for that component, and
is similar to the space component of key. If key (or colorkey for
levelplot and wireframe) is specified, their space component must
not conflict with the name of any component of legend.

Each component of legend must have a component called fun. This
can be a "grob", or a function or the name of a function that produces a
"grob" when called. If this function expects any arguments, they must
be supplied as a list in another component called args. For components
named "inside", there can be additional components called x, y and
corner, which work in the same way as it does for key.

page: a function of one argument (page number) to be called after drawing
each page. The function must be 'grid-compliant', and is called with the
whole display area as the default viewport.

main: typically a character string or expression describing the main title to be
placed on top of each page. Defaults to NULL.main (as well as xlab,
ylab and sub) is usually a character string or an expression that gets
used as the label, but can also be a list that controls further details. Ex-
pressions are treated as specification of LaTeX-like markup as described in
plotmath. The label can be a vector, in which case the components will
be spaced out horizontally (or vertically for ylab). This feature can be
used to provide column or row labels rather than a single axis label.

When main (etc.) is a list, the actual label should be specified as the
label component (which may be unnamed if it is the first component).
The label can be missing, in which case the default will be used (xlab and
ylab usually have defaults, but main and sub do not). Further named
arguments are passed on to textGrob; this can include arguments con-
trolling positioning like just and rot as well as graphical parameters
such as col and font (see gpar for a full list).

main, xlab, ylab and sub can also be an arbitrary "grob" (grid graph-
ical object).

sub: character string or expression (or a list or "grob") for a subtitle to be
placed at the bottom of each page. See entry for main for finer control
options.

par.strip.text: list of parameters to control the appearance of strip text.
Notable components are col, cex, font and lines. The first three con-
trol graphical parameters while the last is a means of altering the height
of the strips. This can be useful, for example, if the strip labels (derived
from factor levels, say) are double height (i.e., contains "\\n"-s) or if the
default height seems too small or too large. The lineheight component
can control the space between multiple lines. Also, the labels can be abbre-
viated when shown by specifying abbreviate = TRUE, in which case
the components minlength and dot (passed along to the abbreviate
function) can be specified to control the details of how this is done.

layout: In general, a Trellis conditioning plot consists of several panels ar-
ranged in a rectangular array, possibly spanning multiple pages. layout
determines this arrangement.

layout is a numeric vector giving the number of columns, rows and pages
in a multi panel display. By default, the number of columns is the number
of levels of the first conditioning variable and the number of rows is the
number of levels of the second conditioning variable. If there is only one
conditioning variable, the default layout vector is c(0, n), where n is the
number of levels of the given vector. Any time the first value in the layout
vector is 0, the second value is used as the desired number of panels per
page and the actual layout is computed from this, taking into account the
aspect ratio of the panels and the device dimensions (via `par("din")`).
The number of pages is by default set to as many as is required to plot all
the panels. In general, giving a high value of `layout[3]` is not wasteful
because blank pages are never created.

**skip**: logical vector (default `FALSE`), replicated to be as long as the number
of panels (spanning all pages). For elements that are `TRUE`, the corresponding
panel position is skipped; i.e., nothing is plotted in that position. The panel
that was supposed to be drawn there is now drawn in the next available
panel position, and the positions of all the subsequent panels are bumped
up accordingly. This is often useful for arranging plots in an informative
manner.

**strip.left**: `strip.left` can be used to draw strips on the left of each
panel, which can be useful for wide short panels, as in time series (or simi-
lar) plots. It is a function similar to `strip`.

**xlab.default, ylab.default**: fallback default for `xlab` and `ylab` when
they are not specified. If `NULL`, the defaults are parsed from the Trellis
formula. This is rarely useful for the end-user, but can be helpful when
developing new Trellis functions.

**xscale.components, yscale.components**: functions that determine
axis annotation for the x and y axes respectively. See documentation for
`xscale.components.default`, the default values of these arguments,
to learn more.

**axis**: function that draws axis annotation. See documentation for `axis.default`.
the default value of this argument, to learn more.

**perm.cond**: numeric vector, a permutation of `1:n`, where `n` is the number of
conditioning variables. By default, the order in which panels are drawn de-
pends on the order of the conditioning variables specified in the `formula`.
`perm.cond` can modify this order. If the trellis display is thought of as
an `n`-dimensional array, then during printing, its dimensions are permut-
ated using `perm.cond` as the `perm` argument to `aperm`.

**index.cond**: While `perm.cond` permutes the dimensions of the multi-
dimensional array of panels, `index.cond` can be used to subset (or reorder)
Margins of that array. `index.cond` can be a list or a function, with be-
havior in each case described below.
The panel display order within each conditioning variable depends on the
order of their levels. `index.cond` can be used to choose a ‘subset’ (in
the R sense) of these levels, which is then used as the display order for that
variable. If `index.cond` is a list, it has to be as long as the number of
conditioning variables, and the `i`-th component has to be a valid indexing
vector for the integer vector `1:nlevels(g_i)` (which can, among other
things, repeat some of the levels or drop some altogether). The result of this
indexing determines the order of panels within that conditioning variable.
To keep the order of a particular variable unchanged, the corresponding
component must be set to `TRUE`.

Note that the components of `index.cond` are in the order of the condition-
ing variables in the original call, and is not affected by `perm.cond`.
Another possibility is to specify `index.cond` as a function. In this case,
this function is called once for each panel, potentially with all arguments
that are passed to the panel function for that panel. (More specifically, if this function has a \ldots argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) For a single conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables. Although they can be supplied in high level function calls directly, it is more typical to use \code{perm.cond} and \code{index.cond} to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the \code{update} method, both can be set to \code{NULL}, which reverts these back to their defaults.

\code{par.settings}: a list that could be supplied to \code{trellis.par.set}. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. When the object is plotted, these settings are temporarily in effect for the duration of the plot, after which the settings revert back to whatever they were before.

\code{plot.args}: a list of possible arguments to \code{plot.trellis}, which will be used by the \code{plot} or \code{print} methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

\section*{Details}

All the functions documented here are generic, with the \code{formula} method usually doing the actual work. The structure of the plot that is produced is mostly controlled by the formula. For each unique combination of the levels of the conditioning variables \(g_1, g_2, \ldots\), a separate panel is produced using the points \((x, y)\) for the subset of the data (also called packet) defined by that combination. The display can be thought of as a 3-dimensional array of panels, consisting of one 2-dimensional matrix per page. The dimensions of this array are determined by the \code{layout} argument. If there are no conditioning variables, the plot produced consists of a single panel.

The coordinate system used by lattice by default is like a graph, with the origin at the bottom left, with axes increasing to left and up. In particular, panels are by default drawn starting from the bottom left corner, going right and then up; unless \code{as.table = TRUE}, in which case panels are drawn from the top left corner, going right and then down. One might wish to set a global preference for a table-like arrangement by changing the default to \code{as.table=TRUE}; this can be done by setting \code{lattice.options(default.args = list(as.table = TRUE))}. In fact, default values can be set in this manner for the following arguments: \code{as.table}, \code{aspect}, \code{between}, \code{page}, \code{main}, \code{sub}, \code{par.strip.text}, \code{layout}, \code{skip} and \code{strip}. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with \(g_1\) varying fastest. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the \code{index.cond} and \code{perm.cond} arguments, possibly using the \code{update} (and other related) method(s).
**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Note**

Most of the arguments documented here are also applicable for the other high level functions in the lattice package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high level plot.

**Examples**

```r
# Not run:
## wait for user input before each new page (like 'par(ask = TRUE)')
old.prompt <- grid::grid.prompt(TRUE)
## End(Not run)
require(stats)

## Tonga Trench Earthquakes

Depth <- equal.count(quakes$depth, number=8, overlap=.1)
xyplot(lat ~ long | Depth, data = quakes)
update(trellis.last.object(),
   strip = strip.custom(strip.names = TRUE, strip.levels = TRUE),
   par.strip.text = list(cex = 0.75),
   aspect = "iso")

# Example with data from 'Visualizing Data' (Cleveland)
# (obtained from Bill Cleveland's Homepage :
# http://cm.bell-labs.com/cm/ms/departments/sia/wsc/, also
# available at statlib)
```
### Constructing panel functions on the fly; prepanel

```r
xyplot(NOx ~ C | EE, data = ethanol,
prepanel = function(x, y) prepanel.loess(x, y, span = 1),
  xlab = "Compression Ratio", ylab = "NOx (micrograms/J)",
  panel = function(x, y) {
    panel.grid(h=-1, v= 2)
    panel.xyplot(x, y)
    panel.loess(x,y, span=1)
  },
  aspect = "xy")
```

### with and without banking

```
plot <- xyplot(sunspot.year ~ 1700:1988, xlab = "", type = "l",
  scales = list(x = list(alternating = 2)),
  main = "Yearly Sunspots")
print(plot, position = c(0, .3, 1, .9), more = TRUE)
print(update(plot, aspect = "xy", main = "", xlab = "Year"),
  position = c(0, 0, 1, .3))
```

### Multiple variables in formula for grouped displays

```
xyplot(Sepal.Length + Sepal.Width ~ Petal.Length + Petal.Width | Species,
  data = iris, scales = "free", layout = c(2, 2),
  auto.key = list(x = .6, y = .7, corner = c(0, 0)))
```

### user defined panel functions

```
states <- data.frame(state.x77,
  state.name = dimnames(state.x77)[[1]],
  state.region = state.region)
xyplot(Murder ~ Population | state.region, data = states,
  groups = state.name,
  panel = function(x, y, subscripts, groups)
  ltext(x = x, y = y, label = groups[subscripts], cex=1,
    fontfamily = "HersheySans"))
```

```
barchart(yield ~ variety | site, data = barley,
  groups = year, layout = c(1,6),
  ylab = "Barley Yield (bushels/acre)",
  scales = list(x = list(abbreviate = TRUE,
    minlength = 5)))
```

```
barchart(yield ~ variety | site, data = barley,
  groups = year, layout = c(1,6), stack = TRUE,
  auto.key = list(points = FALSE, rectangles = TRUE, space = "right"),
  ylab = "Barley Yield (bushels/acre)",
  scales = list(x = list(rot = 45)))
```

```
bwplot(voice.part ~ height, data=singer, xlab="Height (inches)")
```
dotplot(variety ~ yield | year * site, data=barley)

dotplot(variety ~ yield | site, data = barley, groups = year,
   key = simpleKey(levels(barley$year), space = "right"),
   xlab = "Barley Yield (bushels/acre)",
   aspect=0.5, layout = c(1,6), ylab=NULL)

stripplot(voice.part ~ jitter(height), data = singer, aspect = 1,
   jitter = TRUE, xlab = "Height (inches)"
## Interaction Plot

xyplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
   type = "a",
   auto.key =
   list(space = "right", points = FALSE, lines = TRUE))
## longer version with no x-ticks

## Not run:
bwplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
   panel = "panel.superpose",
   panel.groups = "panel.linejoin",
   xlab = "treatment",
   key = list(lines = Rows(trellis.par.get("superpose.line"),
                            c(1:7, 1)),
            text = list(lab = as.character(unique(OrchardSprays$rowpos))),
            columns = 4, title = "Row position"))
## End(Not run)

## Not run:
grid::grid.prompt(old.prompt)
## End(Not run)
